

Perl 5 Constants and Variables 🚧

Perl Constants	Perl pragma to declare constants <b>⚠️</b> but <b>not read-only!</b> See <a href="#">CPAN</a> modules for defining constants by Neil Bowers and <b>Const::Fast</b> and <b>Attribute::Constant</b>				
Perl Variables Names	Scalar Naming Conventions		Array Naming Conventions		All: 1 <sup>st</sup> char: underscore or letter. Never use ALLCAPS
Case sensitive. ASCII by default, <b>UTF-8</b> if the <b>utf8 pragma</b> is used.	<ul style="list-style-type: none"><li>All variables: words_with_underscores</li><li>Local variables: \$lowercase</li><li>Global variables: \$Title_Case</li><li>Constants: \$UPPER_CASE</li></ul>		Same. Array names should be <b>plural</b> . <ul style="list-style-type: none"><li>@locals</li><li>@Global_Arrays</li><li>@CONSTANT_ARRAYS</li></ul>		<ul style="list-style-type: none"><li>Module names are MixedCaseNoUnderscores</li><li>Constants are UPPERCASE_WITH_UNDERSCORES</li><li>Package wide vars are Mixed_Case_With_Underscores</li><li>Functions/methods are lowercase_with_underscores</li></ul>
<b>Scope</b> of variables • <b>Declarations</b> Scope of variables in Perl @Perl Maven	A variable defined without any of the following prefixed keyword is <b>global by default</b> .		With <b>use strict</b> ; Perl warns when globals are used. If using a global is needed, do something like this:		Write <b>use vars qw( \$AUTOLOAD );</b> to pre-declare the <b>\$AUTOLOAD</b> scalar variable and prevent warning.
	<b>my</b>	local, <b>lexical scope</b> , non persistent	Examples:	<b>my</b> @values = (42, 36, 99); <b>my</b> (\$v1, \$v2) = (42, 36);	
	<b>state</b>	Local, <b>lexical scope</b> , persistent	<i>Perl &gt;= v5.10</i>	Restriction: in <i>Perl &lt; v5.28</i> : array and hashes state cannot be initialized in list context.	
	<b>our</b>	Creates a lexical scoped <b>alias</b> to a package (i.e. global) variable. Prevents global variable access warnings when <b>strict 'vars'</b> is active.			
<u>local</u> can be used to locally <b>change</b> the value of Perl special variables.	<b>local</b>	Localizes an existing package variable to the current scope. It's not a declaration. The variable previous value is restored when leaving the scope. <ul style="list-style-type: none"><li>In modern Perl 5, use it to <b>localize modifications to a global variable or hash value</b>. It's a simple dynamic binding mechanism.</li></ul>			
6 kinds of variables types:	1. scalar \$ 2. array @	3. hash % 4. subroutine (code). &	5. <b>format</b> (See <b>write</b> and <b>select</b> ) <ul style="list-style-type: none"><li>how to format output in Perl?, Perl-Formats</li></ul>		6. <b>I/O</b> : file, directory, other handles
Perl types <b>Scalar</b> See: <b>Scalar::Util</b> Archaic use of single quote: \$Dog'days	\$foo	Simple scalar value	\$#days	Last index of array @days .	
	\$days[28]	29 <sup>th</sup> element of array @days	\$days->[28]	29 <sup>th</sup> element of array pointed to by reference \$days.	
	\$days{'Feb'}	Value associated with the <i>Feb</i> key of hash %days	\$days[0][2]	Multi-dimensional array	
	\${days}	Same as \$days, use before alphanumeric.	\$d{99}{'Feb'}	Multi-dimensional hash	
	\$Dog::days	The \$days variable inside the Dog package.	\$d{99, 'Feb'}	Multi-dimensional hash emulation	
<b>list and Array</b> • 0-based indexed (first index is 0). • Last index of array @name is \$#name	<ul style="list-style-type: none"><li>Arrays are initialized by literal lists.</li><li>Lists are always flattened in Perl:</li></ul>		<ul style="list-style-type: none"><li>You can assign a list of values to a list of variables. Useful to swap: (\$val1, \$val2) = (\$val2, \$val1);</li><li>If there are more variables than values: the extra variables are set to <b>undef</b>. Extra values are ignored.</li></ul>		
	<ul style="list-style-type: none"><li>This means that (1, 2, (10, 20, (100, 200), 30, 40), 4) is exactly the same is (1, 2, 10, 20, 100, 200, 30, 40, 4) . Use <a href="#">references</a> to create nested data structures.</li></ul>		<ul style="list-style-type: none"><li>A <i>list</i> is an ordered collection of scalars (of any type).</li><li>An <i>array</i> is a variable that <b>contains a list</b>.</li><li>Reading beyond the end of array returns <b>undef</b></li></ul>		
	@days	Array containing (\$days[0], \$days[1], ... #days[\$#days])	<ul style="list-style-type: none"><li>A <i>list</i> is an ordered collection of scalars (of any type).</li><li>An <i>array</i> is a variable that <b>contains a list</b>.</li><li>Reading beyond the end of array returns <b>undef</b></li></ul>		
	@days[3,4,5]	Array <u>slices</u> containing (\$days[3], \$days[4], \$days[5])			
	@days[3..5]	Array <u>slices</u> containing (\$days[3], \$days[4], \$days[5])			
	<ul style="list-style-type: none"><li>Negative indices used in read access from the end: -1 is last item.</li><li>Use these negative indices to access from the end. <b>Do not compute index with \$#name -3, if the list size is 2, this will give invalid results.</b></li></ul>				
<ul style="list-style-type: none"><li><b>array slices</b> <b>LPo</b> Simple explanation</li></ul>	<ul style="list-style-type: none"><li>Use a slice to select multiple elements from a list, array, or hash.</li><li>Don't use a slice when you know you need exactly one element.</li><li>An lvalue slice imposes list context on the righthand side.</li><li>Assign to array slice to update several values. ➡</li></ul>		my @extracted = (6, 2, 8, 4); my @choices = @digits[@extracted] my \$mod_time = (state \$filename)[9]; @extracted[1, 3] = (7, 9);		my @digits = (0..9); my @one2five = @digits[1..5]; my @premiers = @digit[1, 2, 3, 5, 7];
	<ul style="list-style-type: none"><li><b>Anonymous arrays</b></li></ul>		<ul style="list-style-type: none"><li>Anonymous array := a type of array reference. Use it to build nested data structures.</li><li>Array reference allows Perl to treat the array as a single item.</li></ul>		
<b>Hash/associative array</b> Hashes @ Perl Maven Note: keys are always strings.	%	%days	Associative array (hash): keys-value pairs. Can be initialized as: <ul style="list-style-type: none"><li>my %days = (Jan =&gt; 31, Feb =&gt; \$leap? 29 : 28, ...)</li><li>my %days = ("Jan", 31, 'Feb', \$leap? 29 : 28, ... )</li></ul> Multiple values of a hash can be changed with the following construct:		Initialize a hash slice with array context: @char_to_num{'A' .. 'Z'} = 1 .. 26; my %rating = (ron => 20, al => 50, steve => 80); # use fat comma to quote word left of it. 🐘
	<b>hash slice</b> <b>LPo</b> ➡	@days{'J', 'F'}	Hash slice returning a list containing (\$days{'J'}, \$days{'F'}) .	my @names = ('ron', 'al'); @rating{ @names } = (25, 35); # update ron & al's ratings	
<b>key-value slices</b> <b>LPo</b> ➡	extract/write values:		my scores = @rating{ @names }; @rating { @names } = (45, 55);		
<b>Subroutine</b>	&	&foo	& is needed to create reference to subroutine with \&subroutine_name		
I/O					
Format					
<b>Typeglob</b>	A typeglob is a symbol table structure with the slots of that symbol for the scalar, array, hash, code, format and I/O form of the symbol in the namespace.				
	*	*symbol	See: <a href="#">Object Oriented Perl</a> , section 2.2.4. Typeglobs. <a href="#">Advanced Perl Programming, 1st Edition Section 3.2</a>		
<b>References</b> <b>Perl references intro</b> <b>Perl reference tutorial</b> <b>Reference purpose</b> <b>IntPo</b> • brace around refs: circumfix dereferencing: • simplify with -> • simplify more 🐘 Disambiguate hash references with +{ ...}	A reference is a scalar variable whose value is a pointer to another Perl variable. Use it to <b>build more complex data types</b> . Make reference with \ . The <b>ref</b> built-in returns a string describing the referent: 'ARRAY', 'HASH', 'CODE', 'FORMAT', 'IO', the class name of a blessed object, an empty string if arg is not a reference.				
	my @array = qw( a, b, c); print \$array[1]. # b You can create complex data with references: 🐘 🐘 🐘	my \$array_ref = ['a', 'b', 'c\n']; print \${array_ref}[1]; # b print \$\$array_ref[1]; # b, simpler print \$array_ref->[1]; # b, arrow notation	my %hash = (a=>1, b=>2, c=>3); print \$hash{c}; # 3 ⬅ drop brace around bareword ref. ➡ ⬅ arrow notation is shorter/cleaner ➡	my \$hash_ref = {a=>1, b=>2, c=>3}; print \${\$hash_ref}{c}; # 3 print \$\$hash_ref{c}; # 3, simpler print \$hash_ref->{c}; # 3 with arrow notation	
	my \$data = [0, 1, 2, [40, 50, 60, [100, 200], 70], 8]; print @{\${\${\$data}[3]}[3]}[0], "\n"; #100 print \$data->[3]->[3]->[0], "\n"; # 100 print \$data->[3]->[3]->[0], "\n"; # 100 print \$data->[3][3][0], "\n"; # 100.	<ul style="list-style-type: none"><li>Creale a lexical reference: my \$hash_ref = \%hash;</li><li>Store a ref to an array or hash into an array: push @array \%hash;</li><li>Pass array or hash to subroutine: fct(\@a, \%h); Return from sub: return (\@a, \%h);</li></ul> ⬅ Arrows between subscript are optional.			
<b>Symbolic References</b> With a simple string it refers to the symbols table of the <i>main</i> package. The string can also be <b>fully qualified name</b> , then it uses the specified symbol table.	<ul style="list-style-type: none"><li>⚠️ Symbolic references are very flexible <b>but dangerous</b> and <b>not allowed when use strict is imposed</b>. It's not used often but it's important to know they exist.</li><li>A <i>symbolic</i> reference is a string containing the name of a variable or subroutine in a package's symbol table. They <b>cannot access lexical variables</b>.</li><li>If a symbolic reference is necessary, restrict it's use to a block and relax the warning checks in block with: <b>no strict "refs";</b></li></ul>				
	package main; \$name = "data"; print \${\$name}; push @{\$name}, 42; &{\$name}();	Same as:  print \$main::data; push @main::data, 42; &main::data();	\$sref = "Pkg::var"; \$sref->{level} = "high"; \$val = \$sref->[3]; \$sref->{\$val, 22}; &{"Pkg" . "var"}();	Same as: \$Pkg::var{level} = "high"; \$val = \$Pkg::var[3]; \$Pkg::var(\$val, 22); &Pkg::var();	
<b>postfix dereferencing</b> See: cool new Perl feature: postfix dereferencing	<i>(Perl &gt;= v5.20.0)</i> Instead of using a sigil prefix, it uses a postfix sigil and star. sref: ref to scalar, aref: ref to array, href: ref to hash, cref: ref to code, gref: ref to glob				
	\$sref->\$*; # same as \$aref->@*; # same as	{ \$sref } { \$aref }	\$aref->\$*#; # same as \$href->\$*#; # same as	{ \$aref } #last array idx { \$href }	\$cref->&\$*; # same as \$gref->**#; # same as
Reference to subroutine	Store a ref to a subroutine:	my \$fct_ref = \&the_function;	Indirect calls: with the simpler <u>arrow notation</u> :	<ul style="list-style-type: none"><li>&amp;{ \$the_function } (arg1, arg2);</li><li>\$the_function-&gt;(arg1, arg2);</li></ul>	
	Using an anonymous subroutine, always calling it indirectly:		my \$op = sub { my \$v1 = shift; my \$v2 = shift; return \$v1 ** \$v2; }; say \$op->(10, 4); # prints 10000		
<b>Autovivification.</b> 🐘 <u>What is autovivification?</u> Perl surprise/problem with autovivification	<ul style="list-style-type: none"><li>Unlike most programming languages Perl automatically creates missing parts of arrays, hashes when an undefined value is <b>referenced</b>.</li><li><b>Also see:</b> autovivification in for loop but not assignment?</li></ul>				
	<b>no autovivification;</b> # turn off vivification except for setting value		<b>no autovivification 'exists';</b> # turn it off just for <b>exists</b> checks. <b>See others.</b>		
<b>Closures</b> • <b>Perl closure</b> 🐘 Note how easy it is to create a closure in Perl: a simple block that defines a lexical variable referenced by subroutines defined in that block. The variable is not accessible outside of the block but the subroutines are!	A closure binds its environment and keeps it to use it when invoked. <ul style="list-style-type: none"><li>In the example at right, a greeter function is built and returned, remembering how to greet. It is used like this: my \$fr = make_greeting("Bonjour"); my \$it = make_greeting("Buongiorno"); \$fr-&gt;('Brigitte'); # prints: "Bonjour, Brigitte!\n" \$it-&gt;('Madonna'); # prints: "Buongiorno, Madonna!\n"</li></ul>		sub make_greeting { my \$greet = shift; my \$greet_fct = sub { my \$name = shift; print "\$greet, \$name!\n"; }; return \$greet_fct; } # return ref to internal function		
	A code block defining lexical variable(s) and subroutines consist of a closure too! With the following example, the add_1() subroutine increments the \$count and that's returned by get_count(). The \$count variable cannot be accessed from anywhere else!		{ my \$count; sub add_1 { count += 1; } sub get_count { return count; } } # lexically scoped variables are only accessible inside the block # but the subroutine is not lexical it's visible # in the package (main by default). # The lifetime of the subroutines is the program, keeping the referred-to variables alive!		

• <a href="#">Regexp Variables</a>					
captured sub-patterns	\$<digit>(\$1, \$2, ...)		Capture buffer content		@{^CAPTURE}
String matched	<ul style="list-style-type: none"><li>\$MATCH</li><li>\$&amp;</li></ul>		String matched (compiled regexp)		\${^MATCH}
String preceding match	<ul style="list-style-type: none"><li>\$PREMATCH</li><li>\$'</li></ul>		String preceding match (compiled regexp)		\${^PREMATCH}
String following match	<ul style="list-style-type: none"><li>\$POSTMATCH</li><li>\$'</li></ul>		String following match (compiled regexp)		{^POSTMATCH}
Last capture group	<ul style="list-style-type: none"><li>\$LAST_PAREN_MATCH</li><li>\$+</li></ul>		Most recently closed capture group		<ul style="list-style-type: none"><li>\$LAST_SUBMATCH_RESULT</li><li>\$^N</li></ul>
Match capture key values	<ul style="list-style-type: none"><li>%+<ul style="list-style-type: none"><li>%{^CAPTURE}</li><li>%LAST_PAREN_MATCH</li></ul></li></ul>		Maximum regexp nested group		\${^RE_COMPILE_RECURSION_LIMIT}
Match start offsets	<ul style="list-style-type: none"><li>@LAST_MATCH_START</li><li>@-</li></ul>		Match ends offsets	<ul style="list-style-type: none"><li>@LAST_MATCH_END</li><li>@+</li></ul>	Named captured groups <ul style="list-style-type: none"><li>%{^CAPTURE_ALL}</li><li>%-</li></ul>
Last successful pattern	\${^LAST_SUCESSFUL_PATTERN}		Result of last successful regexp assertion	<ul style="list-style-type: none"><li>\$^R</li></ul>	<ul style="list-style-type: none"><li>\$LAST_REGEXP_CODE_RESULT</li></ul>
regexp debug flag	\${^RE_DEBUG_FLAG}		regexp internal optimization/memory		\${^RE_TRIE_MAXBUF}
• <a href="#">Format Variables</a>	The format mechanism is use to generate printed layouts. It's an old Perl feature but still useful in various places.				
Current value of the write() accumulator for format() lines.	<ul style="list-style-type: none"><li>\$ACCUMULATOR</li><li>\$^A</li></ul>				
Form feed format. defaults to \f	<ul style="list-style-type: none"><li>IO::Handle-&gt;format_formfeed(EXPR)</li><li>\$FORMAT_FORMFEED</li><li>\$^L</li></ul>		Set of characters after which a string may be broken to fill continuation fields	<ul style="list-style-type: none"><li>IO::Handle-&gt;format_line_break_characters EXPR</li><li>\$FORMAT_LINE_BREAK_CHARACTERS</li><li>\$:</li></ul>	
Number of lines left on the page on currently selected output channel	<ul style="list-style-type: none"><li>HANDLE-&gt;format_lines_left(EXPR)</li><li>\$FORMAT_LINES_LEFT</li><li>\$-</li></ul>		Current page length of current output channel	<ul style="list-style-type: none"><li>HANDLE-&gt;format_lines_per_page(EXPR)</li><li>\$FORMAT_LINES_PER_PAGE</li><li>\$=</li></ul>	
Name of current top-page format of output channel	<ul style="list-style-type: none"><li>HANDLE-&gt;format_top_name(EXPR)</li><li>\$FORMAT_TOP_NAME</li><li>\$^</li></ul>		Report format name of output channel	<ul style="list-style-type: none"><li>HANDLE-&gt;format_name(EXPR)</li><li>\$FORMAT_NAME</li><li>\$~</li></ul>	
• <a href="#">Error Variables</a>	The variables <b>\$?</b> , <b>\$!</b> , <b>\$^E</b> , and <b>\$?</b> contain information about different types of error conditions that may appear during execution of a Perl program. They correspond to errors detected by the Perl interpreter, C library, operating system, or an external program, respectively.				
Perl error from the last eval operator	<ul style="list-style-type: none"><li>\$EVAL_ERROR</li><li>\$@</li></ul>		Current state of interpreter	<ul style="list-style-type: none"><li>\$EXCEPTIONS_BEING_CAUGHT</li><li>\$^S</li></ul>	
Current value of C errno integer variable	<ul style="list-style-type: none"><li>\$OS_ERROR</li><li>\$ERRNO</li><li>\$!</li></ul>	<b>\$!</b> returns the system variable <b>errno</b> when used in a numeric context, but returns the string from <b>pererror()</b> when used in string context.	Hash of error names to 0 or 1, set to 1 if current error is this error.	<ul style="list-style-type: none"><li>%OS_ERROR</li><li>%ERRNO</li><li>%!</li></ul>	
OS detected error	<ul style="list-style-type: none"><li>\$EXTENDED_OS_ERROR</li></ul>		<ul style="list-style-type: none"><li>\$^E</li></ul>		
Status returned by last pipe close, backtick command, wait, waited, or system() call.	<ul style="list-style-type: none"><li>\$CHILD_ERROR</li><li>\$?</li></ul>		native status returned by last pipe close , backtick command, wait() or waitpid() or system() call	\${^CHILD_ERROR_NATIVE}	
Current value of warning switch	<ul style="list-style-type: none"><li>\$WARNING</li><li>\$^W</li></ul>		Current set of warning checks enabled by the use warnings pragma	\${^WARNING_BITS}	
• <a href="#">Variables related to the interpreter state</a>	These variables provide information about the current interpreter state.				
Flag associated with the -c switch	<ul style="list-style-type: none"><li>\$COMPILING</li><li>\$^C</li></ul>		The current value of the debugging flags	<ul style="list-style-type: none"><li>\$DEBUGGING</li><li>\$^D</li></ul>	
Current phase of the perl interpreter	\${^GLOBAL_PHASE}		Debugging support. Internal variable.	<ul style="list-style-type: none"><li>\$PERLDB</li><li>\$^P</li></ul>	
Compile-time hints for the perl interpreter. Internal use only	\$^H		Values of compiled statements	%^H	
Taint mode	\${^TAINT}		Safe locale operations availability	\${^SAFE_LOCALES}	
Input/Output Layers. Internal use by PerlIO only.	\${^OPEN}		Unicode Settings of Perl	\${^UNICODE}	
Internal UTF-8 offset caching code state	\${^UTF8CACHE}		State of UTF-8 locale detected by perl at startup.	\${^UTF8LOCALE}	
• <a href="#">File handle Variables</a>	See also: <b>Perl File Handles</b> The following variables are used in the Input/Output handling as well as program arguments.				
Name of current file read from <>	\$ARGV	Command line arguments of the script ← See <b>diamond operator</b> <>. →	@ARGV	Number of arguments minus one	\$#ARGV
Special file handle that iterates over command-line filenames in @ARGV	ARGV	Special file handle that points to currently open output file when doing edit-in-place processing	ARGVOUT		
Output field separator for the print operator	<ul style="list-style-type: none"><li>IO::Handle-&gt;output_field_separator( EXPR )</li><li>\$OUTPUT_FIELD_SEPARATOR</li><li>\$OFS</li><li>\$,</li></ul>		Current line number for the last file handled accessed	<ul style="list-style-type: none"><li>HANDLE-&gt;input_line_number( EXPR )</li><li>\$INPUT_LINE_NUMBER</li><li>\$NR</li><li>\$.</li></ul>	
Input record separator (newline by default)	<ul style="list-style-type: none"><li>\$RS</li><li>\$/</li></ul> <ul style="list-style-type: none"><li>IO::Handle-&gt;input_record_separator( EXPR )</li><li>\$INPUT_RECORD_SEPARATOR</li></ul>		Output record separator	<ul style="list-style-type: none"><li>\$ORS</li><li>\$\</li><li>IO::Handle-&gt;output_record_separator( EXPR )</li><li>\$OUTPUT_RECORD_SEPARATOR</li></ul>	
<b>Auto-flush control</b> <ul style="list-style-type: none"><li>order of output @ Perl Maven</li><li>Suffering from Buffering?</li></ul>	<ul style="list-style-type: none"><li>HANDLE-&gt;autoflush( EXPR )</li><li>\$OUTPUT_AUTOFLUSH</li><li>\$!</li></ul>		Perl activates file buffering by default. Assign 1 to <b>\$!</b> to activate auto-flush.	Last read file handle	\${^LAST_FH}

Perl 5 Input/Output 🚧

Perl I/O	<div><div><ul style="list-style-type: none"><li>open @ perldoc browser</li><li>Writing to files with Perl @ Perl Maven</li><li>open file in-memory @ stackOverflow</li></ul></div><div><ul style="list-style-type: none"><li>Stupid open() tricks @Perl.com:<ul style="list-style-type: none"><li>No explicit filename</li><li>create an anonymous temporary file</li></ul></li></ul></div><div><ul style="list-style-type: none"><li>print to a string</li><li>read lines from a string</li></ul></div></div>				
print, printf, sprintf	<b>print</b> , <b>printf</b> , <b>sprintf</b> (which describes the format) . Note: <b>print</b> , a list operator, is more efficient than <b>printf</b> . print and printf output to stdout by default, but <b>accept a file handle as the first argument if it is NOT followed by a separating comma!</b> (a ' puts it in the list to print!)				
say	use feature qw(say); or use v5.10; (or higher). Like print, but implicitly appends a newline at the end of the list.				
diamond operator <>	<ul style="list-style-type: none"><li>Both &lt;&gt; and &lt;&lt;&gt;&gt; operators read the content of files listed on the command line via @ARGV.</li><li>The &lt;&gt; operator supports shell redirection and pipe operations which &lt;&lt;&gt;&gt; does not allow (for security reasons).<ul style="list-style-type: none"><li>The &lt;&lt;&gt;&gt; operator is always empty.</li></ul></li><li>With &lt;&gt; is used, if there is nothing on the command line of the program or a dash (-) is present the command line identifies stdin. Not so for the &lt;&lt;&gt;&gt; operator.</li><li>The &lt;&gt; operator, depending on what's inside it, is an exact synonym for either the <b>readline</b> or <b>glob</b> function (but this does not apply to the &lt;&lt;&gt;&gt; operator):<ul style="list-style-type: none"><li>If &lt;&gt; contains only a bareword or a simple scalar variable, it compiles to <b>readline</b>, otherwise it compiles to <b>glob</b>.</li></ul></li></ul>				
<div>👉 In-place-editing ⚠️</div> <div>The &lt;&gt; operator tries to duplicate the original file's permission and ownership.</div>	print <>;	← Simple implementation of /bin/cat	print <<>>;	← safer one	Redirection cannot be forced via file names embedding them with. the <<>> operator.
	print sort <>;	← Simple implementation of /bin/sort	print sort <<>>;	← safer one	
	Set \$^I to a backup file extension (such as Emacs "~" or ".bak") to change the behaviour of the <> and <<>> operators and print. In a while (<>) {...} loop, when \$^I is not undef (its default), Perl: <ul style="list-style-type: none"><li>renames currently processed file with the specified extension added,</li><li>opens a new file with the original name</li><li>prints into the new file.</li><li>Any modification goes into the new file: in-place-editing it!</li></ul>		use strict; \$^I = "~"; # rename old file: add '~' to it's name (Emacs-style backup)  while (<>) { s/something/Something else/; # perform any substitution print; }		
perl -i cmdline option	It's also possible to do this on the command line! For example:		perl -p -i~ -w -e 's/something/Something else/g' data*.dat		
<div>Special filehandle names</div> <div>Also See:</div> <ul style="list-style-type: none"><li>File handle Variables section above.</li><li>open</li><li>open::layers</li></ul> <div>Also see process and filehandles inside the Topic: Process Control below.</div>	ARGV	The special filehandle that iterates over command-line filenames in @ARGV. Usually written as the null filehandle in the angle operator <> (or <<>>)			
	ARGVOUT	The special filehandle that points to the currently open output file when doing edit-in-place processing with -i. <ul style="list-style-type: none"><li>Useful when you have to do a lot of inserting and don't want to keep modifying \$_</li></ul>			
	STDIN	<STDIN> : line input operator for the STDIN filehandle (for the <b>standard input</b> ). <ul style="list-style-type: none"><li>Each time &lt;STDIN&gt; is used in scalar context, Perl reads 1 complete line of the standard input and uses it as the value of &lt;STDIN&gt;.<ul style="list-style-type: none"><li>The string includes a line termination character. Use the <b>chomp</b> built-in function to strip it off the variable.</li></ul></li><li>If &lt;STDIN&gt; is read in list context, it returns <b>all lines inside a list!</b> For example, <b>foreach (&lt;STDIN&gt;) { ... }</b> reads the entire stdin in 1 step: \$_ holds it all!</li></ul>			
		while (<STDIN>) { # print all print; # lines of # stdin }	while (defined(\$_ = <STDIN>)) { print \$_; }	The code in the left-most cell is the shortest form. It is equivalent to the code beside it; each line of stdin is stored in the default variable \$_ and the loop stops on end at which time <STDIN> returns undef.	
	STDOUT	standard output			
	STDERR	standard error Note: generally STDERR is not buffered, while STDOUT is buffered by default. Text sent on STDERR may show up before STDOUT. <ul style="list-style-type: none"><li>Print a new line on STDOUT to help flushing it or assign 1 to \$  to activate auto-flush.</li></ul>			
	DATA				
	Using lexical scalar filehandles	<b>open</b> also supports the use of lexical scalar filehandles, a more versatile and safer mechanism. <ul style="list-style-type: none"><li>The file handle can be declared inside the statement as shown below.</li><li>It can also be declared before, but the file handle variable must be <b>undef</b> when the <b>open</b> statement executes, otherwise open uses it as a file handle value.</li></ul>			
	Example from Grinnz:	<ul style="list-style-type: none"><li>open my \$in_fh, '&lt;', \$filename or die "Failed to open \$filename for reading: \$!";</li><li>open my \$out_fh, '&gt;&gt;:encoding(UTF-8)', \$outfile or die "Failed to open \$outfile for appending: \$!";</li></ul>			

Perl 5 Built-in Functions 🚧

Perl Functions Perl syntax	👉 To get information about a Perl function from the command line: use the <b>perldoc -f</b> command. To get information about <b>print</b> use: <b>perldoc -f print</b> This PDF refers to several Perl built-in functions in various places.
⚠️ Cautionary notes	Some of the Perl functions exhibit various limitations and the vary over Perl versions. This section describes the ones I am aware and the proposed alternatives.
<ul style="list-style-type: none"><li><b>each</b> keyword is broken</li><li>Use <b>Var::Pairs</b> instead.</li></ul>	Do NOT use the built-in <b>each</b> . It is broken, as described by <a href="#">Damian Conway</a> in his Modern Perl Best Practice O'Reilly course, section control structure. <ul style="list-style-type: none"><li><b>each</b> is not re-entrant:<ul style="list-style-type: none"><li>nested loops of each over the same hash does not work as expected and will create infinite loop since the nested loop each juts iterates from where the first loop each left it.</li><li>Exiting the loop leaves the state of the each internal pointer at the current location.</li><li>If you use each on the same hash later it will resume from where it left, it will not start form the beginning.</li></ul></li></ul>

Perl 5 Statements 🚧

Perl Syntax	<b>perldoc perlsyn</b> :Perl syntax is free-form. It borrowed concepts from many languages. See <b>perldoc perlttrap</b> for comparisons and differences.	
Comments	Comments start with a # on a line, outside of a string or regular expression.	
Statement separator	Every statement must be terminated by a semicolon, except for the last statement of a block where it is optional. It is however customary to put it anyway.	
No semicolon after a block	A block is not followed by a semicolon. Note, however that <b>eval {}</b> , <b>sub {}</b> , and <b>do {}</b> need explicit termination because these are not <b>compound statements</b> but just terms inside an expression.	
Statement modifiers ⚠️ Do not use with a <b>my state</b> and <b>our</b> .	A simple statement may be followed by a <i>single</i> modifier just before the terminating semicolon: <div><div><div>if EXPR</div><div>while EXPR</div><div>unless EXPR</div></div><div><div>until EXPR</div></div></div> <div><div>for LIST</div><div>foreach LIST</div><div>when EXPR</div></div> ( <i>Perl &gt;= 5.14</i> ) Used in <b>switch statement</b>	
Compound statements	A sequence of statements inside a file, a {} delimited block, or an <b>eval</b> string constitute a scope. <ul style="list-style-type: none"><li>Because hash references are also identified by {}, it may be necessary to put a semicolon after the opening brace to identify a block. As in: <b>{; ... }</b></li><li>Inside all following, a <b>BLOCK</b> is always enclosed by braces, as in <b>{ ... }</b>, even for if statements.</li><li>In loops, the <b>continue</b> control statement identifies a BLOCK that is executed before the loop condition is evaluated again.</li></ul>	
Control flow Statements: <ul style="list-style-type: none"><li><b>if/elsif/else</b></li><li><b>unless/elsif/else</b></li></ul>	if (EXPR) BLOCK if (EXPR) BLOCK else BLOCK if (EXPR) BLOCK elsif (EXPR) BLOCK ... if (EXPR) BLOCK elsif (EXPR) BLOCK ... else BLOCK	unless (EXPR) BLOCK unless (EXPR) BLOCK else BLOCK unless (EXPR) BLOCK elsif (EXPR) BLOCK ... unless (EXPR) BLOCK elsif (EXPR) BLOCK ... else BLOCK
while and unless loops	LABEL while (EXPR) BLOCK # run while EXPR is true LABEL while (EXPR) BLOCK <b>continue</b> BLOCK	LABEL until (EXPR) BLOCK # run while EXPR is false LABEL until (EXPR) BLOCK <b>continue</b> BLOCK
for and foreach loops <ul style="list-style-type: none"><li><b>for</b> loops</li><li><b>foreach</b> loops</li></ul>	LABEL for (EXPR; EXPR; EXPR) BLOCK LABEL for VAR (LIST) BLOCK LABEL for VAR (LIST) BLOCK <b>continue</b> BLOCK	LABEL foreach (EXPR; EXPR; EXPR) BLOCK LABEL foreach VAR (LIST) BLOCK LABEL foreach VAR (LIST) BLOCK <b>continue</b> BLOCK
switch statement	<b>given (EXPR) BLOCK</b> # in <b>switch</b> statements. ( <i>Perl &gt;= v5.14</i> ). <i>It was available in Perl 5.10.0 but did not work properly until 5.10.1</i>	
Iterate over multiple values at a time	LABEL for my (VAR, VAR) (LIST) BLOCK LABEL for my (VAR, VAR) (LIST) BLOCK continue BLOCK LABEL foreach my (VAR, VAR) (LIST) BLOCK LABEL foreach my (VAR, VAR) (LIST) BLOCK continue BLOCK ( <i>Perl &gt;= 5.36</i> )	
Basic Blocks	A BLOCK by itself is semantically equivalent to a loop that executes once, allowing loop control keywords (see below).	LABEL BLOCK LABEL BLOCK <b>continue</b> BLOCK
Defer blocks	A block prefixed by the <b>defer</b> modifier provides a section of code which runs at a later time during scope exit. Requires: <code>use feature 'refer';</code> ( <i>Perl &gt;= 5.36</i> )	

<b>Try Catch exceptions</b>	<ul style="list-style-type: none"><li>The try/catch syntax provides flow control exception handling. This syntax must be first enabled with <code>use feature 'try';</code></li><li>The finally block is experimental. It cannot return, goto or use loop controls.</li></ul>		
	<pre>try BLOCK catch (VAR) BLOCK try BLOCK catch (VAR) BLOCK finally BLOCK</pre>	<pre>use feature 'try'; try {     my \$x = call_a_function();     \$x &gt; 0 or die "Negative not supported";     do_something_with(\$x); } catch (\$e) {     warn "Unable to output a value; \$e"; }</pre>	
<b>Loop control</b>	The following built-in functions can be used inside the above loops.		
 Use the <b>last</b> and <b>redo</b> inside a naked block of code to control looping.	<b>loop control keywords:</b> <ul style="list-style-type: none"><li><b>last</b> : exits the loop.</li><li><b>next</b> : starts the next iteration of the loop.</li><li><b>redo</b> : restarts the loop block without evaluating the condition again.</li></ul>	The <b>last</b> , <b>next</b> , and <b>redo</b> loop control keywords work in the following constructs: <ul style="list-style-type: none"><li><b>while</b> ( condition ) { ... }</li><li><b>until</b> ( condition ) { ... }</li><li><b>for</b> (init; condition; continue) { ... }</li><li><b>foreach</b> array { ... }</li><li>naked block: { ... }</li></ul>	Notes: <ul style="list-style-type: none"><li>The while and foreach loops may have a <b>continue block</b>: executed before evaluating condition again, which corresponds to the 3rd part of a for loop statement. See <a href="#">this @ stackOverflow</a>.</li><li>Blocks can be labelled  as targets to <b>last</b>, <b>next</b>, and <b>redo</b></li></ul>
<b>Specially Named Blocks</b> <b>PHASE BLOCK</b>	5 specially named blocks are run at the various phase of a running program: <b>BEGIN</b> , <b>UNITCHECK</b> , <b>CHECK</b> , <b>INIT</b> and <b>END</b> . See: <a href="#">BEGIN block - running code during compilation</a> . Note the <b>security risk warnings</b> . The <b>BEGIN</b> block is used to implement other Perl functionality.		
<b>Statement modifiers</b>	<ul style="list-style-type: none"><li>if EXPR</li><li>unless EXPR</li><li>while EXPR</li><li>until EXPR</li><li>for LIST</li><li>foreach LIST</li><li>when EXPR</li></ul>	The <b>for</b> and <b>foreach</b> statements <b>impose a list context</b> ; the complete list is processed. Therefore a loop like the following trying to stop on a line that has " __END__ " on it will <b>not work</b> since it reads all of STDIN: <pre>foreach (&lt;STDIN&gt;) {     last if ? __END__ /;     ...; }</pre>	The while statement <b>imposes a scalar context</b> ; it takes one line at a time from <STDIN> and the following code works properly: <pre>while (&lt;STDIN&gt;) {     last if / __END__ /;     ...; }</pre>
<b>do block</b>	<ul style="list-style-type: none"><li>The do block is <b>*very useful*</b> to set a value based on several conditions, just as the <b>? : conditional operator</b> but with an explicit block that may use scoped variables.</li><li>Takes advantage of a block value is the value of the last expression executed inside the block. Do "not" return from the block.</li><li>The last, next and redo cannot be used inside do blocks.</li><li>The do blocks are <i>not</i> semantically equivalent to loop blocks.</li></ul>	<pre>my \$next_step = do {     my (\$perl_nirvana, \$emacs_nirvana) = check-nirvana-levels();     if (\$perl_nirvana &lt; 5 &amp;&amp; \$emacs_nirvana &lt; 8) { 'study-Perl' }     elsif ( some_other_cond() ) { 'time-to-cook' }     elsif ( \$emacs_nirvana &lt; 7 ) { 'look-into-eieio' }     else { \$isit_winter? 'go-skiing' : 'go-canoeing' } }</pre>	
<b>goto statement</b>	Perl supports 3 forms of goto statements: <b>goto-LABEL</b> , <b>goto-EXPR</b> , and <b>goto-&amp;NAME</b> . Note that loops labels cannot be used.		

## Perl 5 Subroutines 🚧

<b>Perl subroutines</b> Object Oriented Perl, 2.1.4	<ul style="list-style-type: none"> <li>Parentheses are optional when calling a subroutine. In some cases, using them prevents mis-interpretations.</li> <li>Also note that blocks are often passed as first argument to a subroutine.</li> </ul>		
<ul style="list-style-type: none"> <li><b>Declaring subroutine</b> In all cases, it's less ambiguous to define the subroutine before use and use parentheses in calls.</li> </ul>	<ul style="list-style-type: none"> <li>Declare a subroutine to use as a list operator. <ul style="list-style-type: none"> <li>use <b>or</b> or not <b>  </b> because it binds too tightly.</li> </ul> </li> <li>Declare a subroutine to use as a unary operator:</li> </ul>	<pre>sub seed_for; \$val = seed_for \$0 or die 'seed_for failed';</pre>	
		<pre>sub seed_for(\$); # use subroutine prototype to declare it as unary operator. \$val = seef_for \$0    die 'seed_for failed';</pre>	
<ul style="list-style-type: none"> <li>Defining subroutine</li> </ul>	<ul style="list-style-type: none"> <li>Defined with the <b>sub</b> keyword followed by a block.</li> </ul>	<pre>sub greet { print "hello!\n"; }</pre>	
<ul style="list-style-type: none"> <li>Calling a subroutine</li> </ul>	<ul style="list-style-type: none"> <li>If the subroutine definition follows its invocation, parentheses after the subroutine name are required, as in: <code>greet()</code>;</li> </ul>	<ul style="list-style-type: none"> <li>But if the definition was above the call, the parentheses are optional; as in: <code>greet;</code></li> <li>Subroutine sigil is &amp;. It can optionally be used in a call; as in <code>&amp;greet;</code> or <code>&amp;greet()</code>;</li> </ul>	
<ul style="list-style-type: none"> <li>pass current @_array</li> <li><b>goto</b></li> </ul>	<ul style="list-style-type: none"> <li>Call with &amp; prefix without args, as in <a href="#">&amp;sub_function</a>; to pass current @_ array. Used to call a helper subroutine with in the primary one, providing all its arguments.</li> <li>From a subroutine use <a href="#">goto &amp;sub_function</a>; to transfer control to that subroutine instead of calling it. It also passes the current @_ array to it.</li> </ul>		
<ul style="list-style-type: none"> <li>calling a method</li> </ul>	<ul style="list-style-type: none"> <li>Parentheses are required if arguments are passed to method, but optional if there is no arguments.</li> </ul>	<pre>\$obj-&gt;method_with_args(\$val1, \$valb); \$obj-&gt;method_without_arg;           \$obj-&gt;method_without_args();</pre>	
<ul style="list-style-type: none"> <li>subroutine &amp;</li> </ul>	<ul style="list-style-type: none"> <li><a href="#">Why we teach the subroutine ampersand</a></li> <li><a href="#">Why should I use the &amp; to call a Perl subroutine? @ StackOverflow</a></li> </ul>	<ul style="list-style-type: none"> <li>Another point of view: <a href="#">Subroutines and Ampersands</a></li> <li>Note it must be used to <a href="#">make a reference</a> to a subroutine: <code>\$greeter = \&amp;greet;</code></li> </ul>	
<ul style="list-style-type: none"> <li>subroutine arguments</li> <li><b>passed by list</b> <ul style="list-style-type: none"> <li>always variable by nature</li> </ul> </li> <li><b>named arguments</b> Note: The <code>@_</code> is an <b>alias</b> to the passed values; changing them inside the subroutine affects the caller's values.</li> </ul>	<ul style="list-style-type: none"> <li>The arguments passed to a subroutine are available to its code via the special <code>@_</code> array. The caller code supplies a list of values. Lists lists are flattened in Perl.</li> <li>Since hash declaration take a list of key/value pairs, it's easy to implement a passing <b>named</b> arguments!</li> <li>It's also possible for the subroutine to set defaults for some of the expected arguments by taking advantage of the fact that hash are lists, list are flattened and hash can be assigned a list with the last values are used.</li> </ul>	<pre>@sorted = alpha_order('Nice', 'Québec', 'Montréal'); @sorted = number_order @unsorted_numbers; @sorted = alpha_order('Trois-Rivières', @sorted, 'Gaspé', 'Rimouski');</pre> <p>Implementation: <code>sub move { my (%directions) = @_; ... }</code>  Caller: <code>move(up=&gt;3, left=&gt;4); move('down', 2);</code> # it's by convention!  To set a default:  <pre>sub move {     %default = (up=&gt;0, down=0, left=&gt;0, right=&gt;0);     my (%directions) = (%default, @_);     ... }</pre></p>	
<b>Subroutine Prototypes</b>	An older Perl feature. Clashes with subroutine signatures as of Perl v5.20. In <i>Perl &gt;= v5.20</i> put the <b>:prototype</b> attribute before subroutine prototype parenthesis.		
<b>Subroutine signatures</b> <ul style="list-style-type: none"> <li><i>Perl &gt;=5.36</i>: Stable</li> <li><i>Perl &gt;= 5.20</i>: Experimental</li> </ul> See: <a href="#">Use v5.20 subroutine signatures</a>	Exactly zero arguments	<code>()</code>	Zero or 1 argument, no default, unnamed: <code>(\$=)</code>
	Zero or 1 argument, no default, named	<code>(\$val=)</code>	Zero or 1 argument, named, with default <code>(\$val=1)</code>
	exactly 1 named argument:	<code>(\$val)</code>	Exactly 2 arguments <code>(\$v1, \$v2)</code>
	2, 3 or 4 arguments no defaults:	<code>(\$v1, \$v2, \$=, \$=)</code>	2,3 or 4 arguments, 1 default: <code>(\$v1, \$v2, \$v3='a', \$=)</code>
	Two or more, any number of arguments.	<code>(\$v1, \$v2, @)</code>	Two or more arguments, remainders into a named array: <code>(\$v1, \$v2, @rest)</code>
	Two or more arguments: an even number	<code>(\$v1, \$v2, %)</code>	Two or more arguments, remainders into a named hash: <code>(\$v1, \$v2, %rest)</code>
	<b>Class method</b>	<code>(\$class, ...)</code>	<b>Object method</b> <code>( \$self, ...)</code>
<b>Returned value.</b>  Detecting calling context with <a href="#">wantarray</a>	<ul style="list-style-type: none"> <li>The result of the last evaluated expression is implicitly returned.</li> <li>The <b>return</b> operator can be used but it's not required unless used to change execution flow (return immediately from the subroutine).</li> <li>The subroutine can return a scalar in scalar context or a list if called in list context. <ul style="list-style-type: none"> <li>Inside the subroutine, use the <a href="#">wantarray</a> function to determine the calling context of the subroutine call and why it should return:</li> </ul> </li> </ul>		
<b>Identify caller</b>	The <a href="#">caller</a> built-in returns information about the subroutine caller inside an array: ( package, file_name, file_line). In scalar context it returns the package only.		
<b>AutoLoading</b>	On a call to undefined subroutine Perl checks if the package defines an <b>\$AUTOLOAD</b> subroutine it calls that.		Also see: <b>AutoLoader</b> .
<b>Continuation with goto</b>	The <a href="#">goto</a> built-in can be used by a subroutine to continue its execution into another subroutine. Not for all but useful in some specific cases such as <a href="#">autoloading</a> .		

## Perl 5 Classes, Objects and Methods 🚧

<b>Object Oriented Perl</b> <ul style="list-style-type: none"> <li><b>Perl OO Tutorial</b></li> <li><b>Perl Module Library</b> <ul style="list-style-type: none"> <li><b>Module creation guideline</b></li> </ul> </li> </ul>	To build a Perl class with common Perl: <b>1)</b> create a package with the name of the class inside a module, <b>2)</b> write functions in the package, <b>3)</b> <a href="#">bless</a> a referent.
	<ul style="list-style-type: none"> <li>By convention, something a name that starts with an underscore is <i>internal</i>, not meant to be used directly. <ul style="list-style-type: none"> <li>There is nothing preventing direct access, but users of the class should not access it directly (as OO design principles recommend).</li> </ul> </li> <li>Perl ignore prototypes of methods.</li> <li>It's possible to create class methods and class attributes: Their scope must be the scope of the module they are defined in.</li> <li><b>Destructors</b> are normally not required, as Perl automatically destroys objects at their end-of-life based on scope. It's needed when classes use circular references. <ul style="list-style-type: none"> <li>It is possible to create explicit destructor by defining a <b>DESTROY</b> method in the class. See <a href="#">The destructor called DESTROY</a> and <a href="#">Object Oriented Perl</a> book.</li> </ul> </li> <li><b>Inheritance</b>: parent classes are identified in the <a href="#">@ISA array</a>. In code set them by identifying them via the <a href="#">use parent pragma</a>. <ul style="list-style-type: none"> <li>See the <a href="#">isa</a> class instance operator.</li> </ul> </li> </ul>

<div>Other:</div> <div><div><div>• <a href="#">Object Oriented Perl</a> by Damian Conway</div><div>• <a href="#">Corinna Class Tutorial</a></div></div></div> <div>See also Perl extension for OO:</div> <div><div><div>• <a href="#">Perl Moose @ wikipedia</a></div><div>• <a href="#">Moose home</a></div><div>• <a href="#">Moose @ meta::Cpan</a></div></div></div>	<pre>use Employee; use strict;  # By using the package name and the arrow operator to refer # to the new method, Perl passes the string "Employee", the # class name, to the first argument. This is used by the <a href="#">bless</a> # built-in to turn the anonymous hash <a href="#">objref</a> into an # Employee class reference.  my \$empl = Employee-&gt;new('Pete', 'V.P.');</pre> <div># The Employee::new method returns a reference to the # object. It can be used to call other methods, which also # pass the object reference as the first argument.</div> <pre>\$empl-&gt;set_office('L1-100');</pre> <div>Note the that calling Employee::new directory, no object reference is passed; therefore the arrow nation is required.</div>	<pre>package Employee;      # a very simple/naive class implementation  sub new {              # A class construction method, conventional name: new     my \$class = \$_[0]; # first argument is class name (a string)     my \$objref = {      # following arguments passed to Employee-&gt;new()         _name = \$_[1],  # by convention, names of class attributes start with         _role = \$_[2],  # an underscore. Access them only inside the methods     };                  # but Perl provides no access protection.     ...     <a href="#">bless</a> \$objref, \$class; # bless object referent as a class, return it from new() }  sub set_office {        # first argument is the class instance     my (\$self, \$office_ID) = @_; # it's assigned to self: the reference to the object     \$self-&gt;{_office_ID} = \$office_ID; }</pre>
The <a href="#">tie</a> function	The <a href="#">tie</a> function is used to associate a behaviour provided by package subroutines to a specific a variable or handle. <div>• It's possible to tie operations on a scalar, array, hash or handle to a specific variable. The operations are controlled by the package subroutines that have preselected names for various operations depending on the type selected (scalar, hash, array or handle).</div>

## Perl 5 Modules

Perl Modules	Note that module files must end with a true value. It is customary to place a <b>1</b> ; on the last non-commented line that.		
Perl core modules	<ul style="list-style-type: none"><li>How to detect where a module is installed : <a href="#">perldoc -l Module</a></li><li>How to check if a module is part of Perl core : <a href="#">corelist</a> Module (Perl &gt;= v5.9.2)</li></ul>		
Access to Modules	Provide access to modules in your code with one of the following: <a href="#">do</a> , <a href="#">require</a> or <a href="#">use</a>		
Modules @perltutorial Modules Using simple modules 	<a href="#">do</a>	<p>Looks for the module file by searching the <a href="#">@INC</a> path. Performed <b>at run time</b> (and therefore can be done conditionally).</p> <ul style="list-style-type: none"><li>If Perl finds the file, it places the code inside the calling program and executes it. Otherwise, Perl will skip the do statement silently.  The "included" code does not have access to the lexical variables from the main program.</li><li>Skip the <a href="#">@INC</a> path lookup if given a file path starting with <code>./</code>, <code>../</code>, or <code>/</code></li></ul>	
The <i>normal</i> way to access Perl modules ➡	<a href="#">require</a>	<p>Loads the module file once, also searching the <a href="#">@INC</a> path. Performed <b>at run time</b> (and therefore can be done conditionally).</p> <ul style="list-style-type: none"><li>If the <a href="#">require</a> for the same file appears twice, Perl ignores it. Perl will issue an error message if it cannot find the file (as opposed to <a href="#">do</a>).</li><li>Skip the <a href="#">@INC</a> path lookup if given a file path starting with <code>./</code>, <code>../</code>, or <code>/</code></li></ul>	
	<a href="#">use</a>	<p>Similar to <a href="#">require</a> except that Perl applies it before the program starts: it's <b>done at compile time</b>. Modify it dynamically in a <a href="#">BEGIN</a> block. See <a href="#">IntPor</a>.</p> <ul style="list-style-type: none"><li>Therefore the <a href="#">use</a> statement cannot be invoked inside conditional statements such as if-else. Used often to include a module in a program. That imports the defaults as defined by the module's code.</li></ul> <p>Select what to import with one of the two equivalent forms: (See <a href="#">IntPor</a>):</p> <ul style="list-style-type: none"><li><a href="#">use</a> Module::Name ('function_a', 'function_b');</li><li><a href="#">use</a> Module::Name <a href="#">qw( function_a function_b )</a>;</li><li><a href="#">use</a> Module::Name (); # import nothing. All accesses to the module must be done with Module::Name::something</li></ul>	
Error handling for: <b>Can't locate in @INC</b> <ul style="list-style-type: none"><li>How to fix that</li></ul>	<p>For the above statements to work Perl must be able to identify the location of the requested module(s).</p> <ul style="list-style-type: none"><li>Perl looks for a module code inside the directories identified by the <a href="#">@INC</a> array.</li></ul> <p>if you have. <a href="#">use</a> The::Module; inside your code, Perl looks for a sub-directory named 'The' containing a file named 'Module.pm' inside each <a href="#">@INC</a> directory.</p> <p>If Perl does not find it, there are <a href="#">multiple ways to solve the problem</a>:</p> <ul style="list-style-type: none"><li>Add the required directory to the list of directories identified in the ':' separated list in the PERL5LIB environment variable. ( use ';' as separators in Windows).</li><li>Add a <a href="#">use lib</a> 'path/to/the/directory'; statement inside your Perl file to add the required directory when executing a specific piece of Perl code, at compile time.</li><li>Run Perl with the <a href="#">-I (capital i) option</a> to run the code with the extra directory added to <a href="#">@INC</a> array.</li></ul> <p>To List the directories used by Perl from one of the following equivalent command lines:</p> <ul style="list-style-type: none"><li>perl -e 'print join("\n", @INC), "\n";'</li><li>perl -le 'print for INC;'</li></ul> <p>You can also get more information with <code>perl -v</code></p>		
Declare <b>packages</b>	<p>In Perl a package can span several files and one file may contain the code of several packages.</p> <p>The package starts with the <a href="#">package</a> keyword. The special <a href="#">__PACKAGE__</a> literal contains the name of the current package.</p> <ul style="list-style-type: none"><li>The default package is the main package. Code at the before the first package declaration in a file belongs to the main package.</li></ul>		

## Topic: Data Introspection

Data Introspection					
Using <a href="#">Perl Debugger</a> • <a href="#">Debugger Tutorial</a>	Debug a program:		<a href="#">perl -d</a> program_name program_args		
	Debug interactive session:		<a href="#">perl -d -e 0</a>		
Debugger commands	<a href="#">q</a>	Quit debugger	<a href="#">s</a>	single step	
	<a href="#">h</a>	help. List all available commands.	<a href="#">x</a>	evaluate expression	
Modules for Data introspection	<a href="#">Data::Dumper</a> <i>(Perl &gt;= 5.005)</i> It provides the Dumper function that prints strings that can be used by <a href="#">eval</a> to rebuild the data.		<ul style="list-style-type: none"><li>It is similar to the x command of the debugger.</li><li>Pass reference to the variables , otherwise it extends them to list and show each entry as its own variable.</li></ul>		<ul style="list-style-type: none"><li><a href="#">print Dumper(\@array);</a></li><li><a href="#">print Dumper \%hash;</a></li></ul>
	<a href="#">Data::Dump</a> <i>(Requires Perl &gt;= v5.6.0)</i>		Provides a dump function that has nicer output, but is not <a href="#">eval</a> compatible. <ul style="list-style-type: none"><li>dump() prints on the stdout. No need to use print.</li></ul>		<a href="#">use Data::Dump qw(dump);</a> <a href="#">dump( \@array);</a> <a href="#">dump( \%hash );</a>
	<a href="#">Data::Printer</a> A nicer data dumper, not <a href="#">eval</a> compatible.		<ul style="list-style-type: none"><li>It provides the <a href="#">p</a> subroutine that does not require a reference to the variable as it inspects it first.</li><li>p() prints on the stdout. No need to use print.</li></ul>		<a href="#">use Data::Printer;</a> <a href="#">p(@array);</a> <a href="#">p(%hash);</a>
<a href="#">Data Marshalling</a> • <a href="#">Data Serialization</a>	There are several modules, either part of Perl core or outside, that provides mechanism to marshal/serialize and unmarshal/de-serialize data. <ul style="list-style-type: none"><li>See the links at left for more info.</li></ul>				
<a href="#">perl-live-coding</a> • <a href="#">Demo screencast</a>	This third party package creates a very good Perl REPL. It can be used outside and inside of <a href="#">Emacs</a> . <ul style="list-style-type: none"><li>When used inside Emacs it can evaluate Perl code by line, marked area and display the results in a secondary buffer. Highly recommended.</li></ul>				

Topic: Directory Operations 🚧

Directory Operations	In Books: <b>LPo</b>		
Opening Files	All file open operations are relative to the <i>current working directory</i> (for relative file names)		<code>open my \$filehandle, '&lt;:utf8', 'a_relative/path.txt'</code>
Creating temporary files	<b>File::Temp</b> (Perl >= v5.6.1). Using <code>File::Temp</code> . Also see <b>IO::File</b>		
Built-in Functions	Related Functions/Packages / Descriptions		Notes
Getting file names by: • <b>Globbering</b> : • with <b>glob</b>       • with the glob operator <>	<b>File::Glob</b> (Perl >= v5.6.0) - provides more control.	Example:	<code>my @all_files = glob '*'; my @perl_files = glob '*.pm *.pl'; # 2 globs, space-separated</code>
	The <> operator is identifying: • a <b>filehandle</b> , when: the item inside <> is a Perl identifier or an indirect file handle read scalar, • a <b>glob expression</b> otherwise.	Glob examples:	<code>my @all_files = &lt;'*&gt;; my @all_files = &lt;*&gt;; # 1 glob: no space, no need for string my @perl_files = &lt;'*.pm *.pl*&gt;; # 2 globs, space-separated  my \$etc_dir = '/etc'; my @etc_dir_files = &lt;\$etc_dir/* \$etc_dir/*.*&gt;;  my @files = &lt;LARRY/*&gt;; # a glob</code>
			<code>my @this_lines = &lt;LARRY&gt;; # a filehandle read  my \$name = 'LARRY'; my @this_lines = &lt;\$name&gt;; # indirect filehandle read of LARRY handle my @same_lines = readline LARRY; # another way to write above my @same_lines = readline \$name;</code>
	See: <b>readline</b>	Filehandle examples:	
• with a directory handle <b>LPo</b>	• <b>opendir</b> : open a directory: get a directory handle • <b>readdir</b> : read the directory handle. <b>But see this</b> . • <b>closedir</b> : close the directory handle. • <b>DirHandle</b> (Perl <= 5.5) • <b>File::Spec::Functions</b> (Perl >= v5.5.4) • <b>Path::Class</b>	Example: iterate explicitly over a list of file names extracted from the directory using these 3 functions.	<code>my \$dir = '/usr/bin'; <b>opendir</b> my \$dh, \$dir or die "Failed opening \$dir: \$!"; foreach \$file (<b>readdir</b> \$dh) {   print "File \$file is inside \$dir\n"; # ⚠ no path in name! } <b>closedir</b> \$dh;</code>
Creating directory	• <b>mkdir</b>	Example:	<code>mkdir \$dir_name, oct(\$permissions); # octal for permissions mkdir \$dir_name, 0700; # do not use "0700", it's 700 decimal!</code>
Removing directory	• <b>rmdir</b> Removes an <b>empty</b> directory. • <b>File::Path remove_tree</b> , <b>rmtree</b> remove dir & files (Perl >= v5.0.1)		
Removing files	• <b>unlink</b> a list or <b>\$</b>		<code>unlink 'file1.txt', 'file2.txt'; unlink qw( file1.txt file2.txt); unlink glob 'file?.txt'</code>
Renaming files	• <b>rename</b> an old file name to a new one. • The fat comma operator is sometimes used to highlight what is the old and the new name.	As in here:	<code>rename 'old_name' , 'new_name'; rename  old_name =&gt; 'new_name'; # use <b>fat comma</b> to quote word left of it.</code>
Changing permissions	• <b>chmod</b> changes file permissions		
Changing ownership	• <b>chown</b> changes file ownership		
Creating <b>Hard</b> link	• <b>link</b> to create a hard link		
Creating <b>symbolic</b> link	• <b>symlink</b> to create a symbolic link		
<b>chdir</b> Change current working directory	• <b>File::chdir</b> • <b>File::HomeDir</b>	• Change the current working directory. • <b>chdir</b> without argument attempt to change to user home directory using the <code>\$ENV{HOME}</code> and <code>\$ENV{LOGDIR}</code> environment values <b>if</b> ⚠ they are set. The <b>File::HomeDir</b> module helps in setting them. • The built-in <b>chdir</b> is global ⚠ for the entire program. Use <b>File::chdir</b> facilities for localized operations.	
Modules	Functions	Extra Information	
	<b>Legend: Exported by default</b> , exported on request, <i>Win32 specific</i>		
<b>Cwd</b>	• <b>getcwd</b> , <b>cwd</b> , <b>fastcwd</b> , <b>fastgetcwd</b> , <i>getdcwd</i> • <i>abs_path</i> , <i>realpath</i> , <i>fast_abs_path</i>		<code>use Cwd; my \$curdir = getcwd; print "cwd is \$curdir\n";</code>
<b>File::Basename</b>	• <b>fileparse</b> , <b>basename</b> , <b>dirname</b> ,		
<b>File::Spec</b> <b>File::Spec::Functions</b>	• functional interface to methods: <b>canonpath</b> , <b>catdir</b> , <b>catfile</b> , <b>curdir</b> , <b>rootdir</b> , <b>updir</b> , <b>no upwards</b> , <b>file name is absolute</b> , <b>path</b> . <i>devnul</i> , <i>tmpdir</i> , <i>case tolerant</i> , <i>splitpath</i> , <i>splitdir</i> , <i>catpath</i> , <i>abs2rel</i> , <i>rel2abs</i> . All can be imported by using the <code>:ALL</code> tag.		
<b>File::Find</b> : Traverse a directory tree. See: <b>File::Find::Closures</b>	<b>find</b> , <b>finddepth</b> , <b>%options</b> . In <b>wanted</b> : <b>File::Find::dir</b> , <b>File::Find::name</b> Note that <b>\$</b> gets the base name of the file (no path). It is used to perform filetest operations in the example here (as explicit argument to -s, and implicit argument to -d and -f). This traverses the <b>entire</b> tree.		<code>use <b>File::Find</b>; <b>find</b>(sub {printf("- %-10s : %4d, %s\n", \$_, -s \$_, <b>File::Find::name</b>)           if (-d or -f) and ( \$ _ ne "."); }, '.'); # in the above it lists the names of files inside all directories not showing the directory name</code>

Topic: List Operations 🚧

List Operators			
Sorting lists	<b>sort</b>	Sort a list	<code>my @sorted = sort @unsorted_list;</code> in place: <code>my @data = <b>sort</b> @data;</code>
	<b>reverse</b>	Sort a list in reverse order	<code>my @rsorted = <b>reverse</b> @unsorted_list;</code> in place: <code>my @data = <b>reverse</b> @data;</code>
Filtering list with <b>grep</b>	<code>my @adult_ages = <b>grep</b> \$_ &gt; 18, @ages;</code>		<code>my @lucky_ages = <b>grep</b> /7\$/, @ages; # all that end with 7</code> <code>my @read_ages = <b>grep</b> { \$_ &gt;= 7 &amp;&amp; \$_ &lt;= 77 } @ages;</code>
Counting matches	<code>my \$count = <b>grep</b> \$_ &gt; 18, @ages;</code>		
	An expression, subroutine or block with trailing boolean can be used as the grep criteria. Each item in the list is identified inside grep by <b>\$</b> • The block is an anonymous subroutine. 🙌 Return a boolean from the subroutine, but fall-off, do not return, from a block!		
Transform a list with <b>map</b>	• <b>map block LIST</b> • <b>map EXPR, LIST</b>	Evaluates the BLOCK or EPR for each element of LIST, setting <b>\$</b> to each element, composing a list with the results.	Each element can generate a single value, a list or 0 or more elements. The result list flattened anyway.

Topic: Process control 🚧

Process Control	In Books: <b>LPo</b>		Important security information: <b>perldoc perlsec</b>	
Environment Variables	Inside the <b>%ENV</b> hash.	Perl <b>%Config</b> hash: Perl configuration information. For example, whether it support threads, what are path separators, etc... <ul style="list-style-type: none"><li>To use it: <code>use Config;</code></li></ul>		
Built-in Functions	Example	Description/ Notes		
<b>system</b> (2 functions) <ul style="list-style-type: none"><li>using the shell<ul style="list-style-type: none"><li><b>security risk?</b></li></ul></li><li>avoiding the shell</li><li>other syntax</li></ul>	<b>system</b> 'ls -l \$HOME';	Run child process asynchronously using parent's stdin, stdout and stderr, using the OS native command shell.		
	<b>system</b> "cd \$project; make &";	Use the Unix shell to execute a long running build asynchronously. 🙌 However: <b>avoid using the shell like this</b> . <ul style="list-style-type: none"><li>Using the shell to build commands from unvalidated user input data <b>may lead to security issues</b>.</li></ul>		
	<b>system</b> 'tar', 'cvf', \$tarfile, @directories;	No shell invoked when more than 1 argument is passed to system. No shell interpretation, piping, re-direction done.		
	<b>system</b> ( 'tar', @arguments);	0 means success: <code>unless ( <b>system</b> 'tar', arguments) { print "tar command success\n"; }</code>		
	<b>system</b> ( { \$prog }, \$arg0, @args);			
	👉 Note that if the string contain <b>no</b> shell <b>metacharacters</b> it is executed directly (not through a shell).			

<div><div>system</div> return value:</div> <ul style="list-style-type: none"><li>A value of 0 <i>usually</i> means all was OK.</li></ul>	2 bytes:	MSByte: child program exit code.	my \$retval = <u>system</u> ( ... );	← shift most significant byte
		LSByte: system-specific information bits: <ul style="list-style-type: none"><li>0x80 : set on core dump.</li><li>0x7f : <u>signal</u> number</li></ul>	my \$childp_exitcode = \$retval >> 8; my \$had_core_dump = (\$retval & 0x80) == 0x80? 1 : 0; my \$signal_number = \$retval & 0x7f;	← use least significant byte
exec	Unlike system, <u>exec</u> does not return to the parent Perl process. Use: <u>exec</u> 'the_program' or <u>die</u> "Could not run: \$!"; #or <u>warn</u> or <u>exit</u>			
backquotes ``	Use backquotes to <b>capture the stdout</b> of a program. That's the main point of using it. <ul style="list-style-type: none"><li>The trailing newline is not filtered out; it can be filter by <u>chomp</u>.</li></ul>		<u>chomp</u> ( my \$current_date = `date` );	
	<ul style="list-style-type: none"><li>The value inside the backquotes is treated like the single double quote string argument of <u>system</u>: it will invoke the shell if there are any shell meta-characters and supports interpolation.<ul style="list-style-type: none"><li>The following example builds a dictionary (hash) of topics with the text extracted from perldoc.</li></ul></li><li>Note that ``...`` is also written as <u>qx/ ... /</u></li><li>backquote operation in scalar context returns 1 string. In list context it returns a list of strings (1 per line).</li></ul>		<pre>my @topics = qw( die warn exit ); my %info; foreach (@topics) {     \$info{\$_} = `perldoc -t -f \$_`; }</pre>	
Modules				
Capture streams	<ul style="list-style-type: none"><li><u>Capture::Tiny</u></li></ul>	Can be used to capture the stdout and stderr streams for various ways if executing other programs		
Inter-process support	<ul style="list-style-type: none"><li><u>IPC::System::Simple</u></li></ul>	Can also be used to capture streams and provide more inter-process support. <ul style="list-style-type: none"><li>It provides <b>systemx</b> which never uses the shell, along with other useful functions.</li></ul>		
Processes as filehandles	In Books: <u>LPo</u>			
Perl ← program	Launching a process that pipes into the Perl process	open DATE, 'date  ' or die "Cannot pipe from date: \$!";	Use a bare word to define the DATE file handle.	
		open my \$date_fh, ' -', 'date' or die "Cannot pipe from date: \$!";	This one and the others define a local file handle variable. The file handle variable can later be used to read, as the above one, but is not global.	
		open my \$ps_fh, ' -', 'ps', 'aux' or die "Cannot pipe from ps: \$!";		
		open my \$find_fh, ' -', 'find', qw( . -name '*.p[lm]' -print ) or die "Cannot pipe from find: \$!";		
Perl ➡ program	Launching a process that the Perl process pipes into.	open my \$dispatcher_fh, ' -', 'dispatcher', qw ( '—to-perl-groups' 'Help!' ) or die "Cannot pipe to the dispatcher: \$!";		
Forking	In Books: <u>LPo</u> . See also: Linux <u>fork(2)</u> system call, QA: <u>Why do we need fort to create new processes?</u> <u>Why fork woks the way it does?</u>			
<div><div>fork</div> with <u>exec</u> and <u>waitpid</u></div> <div>See also:<ul style="list-style-type: none"><li><u>Other IPC functions</u></li><li><u>Perl IPC</u></li></ul></div>	<ul style="list-style-type: none"><li>fork the process into parent and child.</li><li>in the child process start the program with exec</li><li>In the parent process wait for the program termination with waitpid</li></ul>	<pre>defined(my \$process_id = <u>fork</u>) or die "Fork failed: \$!"; unless (\$process_id) {     # Inside the child process (created by fork)     <u>exec</u> 'long_running_process' or die "Failed starting long_running_process: \$!"; } # Inside the parent process, wait for completion of long_running_process. <u>waitpid</u>(\$process_id, 0);</pre>		
Signals	In Books: <u>LPo</u>			
kill	Sends a signal to a list of processes. <ul style="list-style-type: none"><li>The signal may be identified by number or name (string), which is more portable.</li><li>The <u>%Config{sign_name}</u> provides the supported signal names.</li><li>Note that the <i>fat comma</i> operator (=&gt;) can be used to automatically quote signal name:</li></ul>		<u>kill</u> 'INT', \$pid or die "Can't signal \$pid with SIGINT: \$!";	
	<ul style="list-style-type: none"><li>If the signal is 0 or "ZERO" no signal is sent to the process; instead Perl checks if it's possible to send a signal to the process: ie: if the process exists.</li></ul>		<u>kill</u> INT => \$pid or die "Can't signal \$pid with SIGINT: \$!";	
	<ul style="list-style-type: none"><li>If the signal is a negative number or a string that starts with '-' the signal is sent to the process group identified by the process scalar argument.</li></ul>		<ul style="list-style-type: none"><li><u>kill</u> '-KILL', \$process_group</li><li><u>kill</u> -9, \$process_group</li></ul>	
	Signal handlers		<u>\$SIG</u> { 'INT' } = 'dispatcher_int_handler';	
Error Logging and Reporting	<ul style="list-style-type: none"><li>Perl supports the warn built-in to generate warnings on stderr.</li><li>The <u>Carp::carp</u> from the <u>Carp</u> package, provides more information.</li></ul>	<ul style="list-style-type: none"><li><u>Log::log4perl</u> is an implementation of the popular Apache <u>Log4j</u> for Perl.</li></ul>		

## PerlTidy formatting control

perltidy option	Option	Impact
<b>indentation style</b>	<ul style="list-style-type: none"> <li>-bl,</li> <li>--opening-brace-on-new-line</li> <li>--brace-left</li> </ul>	<ul style="list-style-type: none"> <li>Without this option (the default) the code indentation style selected is <b>K&amp;R style</b>.</li> <li>With this option, the indentation style is <b>Allman/BSD style</b>.</li> </ul>
