                                                   The $days variable inside the Dog package.
                                                                                                              $d{99, 'Feb'}
                                                                                                                                   Multi-dimensional hash emulation
                              $Dog::days
                              · Arrays are initialized by literal lists.
                                                                                  • You can assign a list of values to a list of variables. Useful to swap: ($val1, $val2) = ($val2, $val1);
list and Array

    If there are more variables than values: the extra variables are set to <u>undef</u>. Extra values are ignored.

· 0-based indexed (first
                                Lists are always flattened in Perl:
  index is 0).
                                • This means that (1, 2, (10, 20, (100, 200), 30, 40), 4) is exactly the same is (1, 2, 10, 20, 100, 200, 30, 40, 4). Use references to create nested data structures.
  Last index of array
  @name is $#name
                                                                                                             • A list is an ordered collection of scalars (of any type).
                                                Array containing ($days[0], $days[1], ... #days[$#days])
                              @days[3,4,5] Array slices containing ($days[3], $days[4], $days[5])
                                                                                                             • An array is a variable that contains a list.
                              @days[3..5] Array slices containing ($days[3], $days[4], $days[5])
                                                                                                              · Reading beyond the end of array returns undef

Negative indices used in read access from the end: -1 is last item.
Use these negative indices to access from the end. Do not compute index with $#name -3, if the list size is 2, this will give invalid results.

                                                                                                              my @extracted = (6, 2, 8, 4):
                                                                                                                                                         my @digits = (0..9):
· array slices LPo
                                Use a slice to select multiple elements from a list, array, or hash.
                                                                                                             my @choices = @digits[@extracted]
my $mod_time = (state $filename)[9];
                                                                                                                                                        my @one2five = @digits[1..5];
my @premiers = @digit[1, 2, 3, 5, 7];
    Simple explanation
                                Don't use a slice when you know you need exactly one
                                An Ivalue slice imposes list context on the righthand side.

    Assign to array slice to update several values. ➡

                                                                                                              @extracted[1, 3] = (7, 9);

    Anonymous arrays

                                What are the advantages of anonymous array? @ StackOverflow
                                                                                                             • Anonymous array := a type of array reference. Use it to build nested data structures.

    Array reference allows Perl to treat the array as a single item.

                                Perlref @ Perldoc. Perl reference tutorial @ Perldoc
Hash/associative array
                                           %days
                                                                Associative array (hash): keys-value pairs. Can be initialized as:
                                                                                                                                                  Initialize a hash slice with array context:
                                                                                                                                                  @char_to_num{'A' .. 'Z'} = 1 .. 26;
my %rating = (ron => 20, al => 50, steve => 80);
Hashes @ Perl Maven
                                                                   my %days = (Jan => 31, Feb
my %days = ("Jan", 31, 'Feb
                                                                                                   Feb => $leap? 29 : 28, ...)
'Feb', $leap? 29 : 28, ...
Note: keys are always
                strings.
                                                                    Multiple values of a hash can be changed with the following construct:
                                                                                                                                                   # use fat comma to quote word left of it. 9
hash slice LPo
                                                                                                                                                   my @names = ('ron', 'al');
                                           @rating{ @names } = (25, 35); # update ron & al's ratings
key-value slices LPor ⇒
                                                               my scores = @rating{ @names }; @rating { @names } = (45, 55);
                                       extract/write values:
Subroutine
                                                                & is needed to create reference to subroutine with \&subroutine name
                                           &foo
Format
                              A typeglob is a symbol table structure with the slots of that symbol for the scalar, array, hash, code, format and I/O form of the symbol in the namespace.
Typeglob
                                                              See: Object Oriented Perl, section 2.2.4. Typeglobs. Advanced Perl Programming, 1st Edition Section 3.2
                              A reference is a scalar variable whose value is a pointer to another Perl variable. Use it to build more complex data types. Make reference with \. The ref built-in
References
                              returns a string describing the referent: 'ARRAY', 'HASH', 'CODE', 'FORMAT', 'IO', the class name of a blessed object, an empty string if arg is not a reference.

                                                                            '\n"; #100
• simplify more
 Disambiguate hash
                                                                                  # 100
references with +{ ...}
                              print $data->[3][3][0],

    Arrows between subscript are optional.

Symbolic References
                              🔥 Symbolic references are very flexible but dangerous and not allowed when use strict is imposed. It's not used often but it's important to know they exist.
With a simple string it refers to the symbols
                              • A symbolic reference is a string containing the name of a variable or subroutine in a package's symbol table. They cannot access lexical variables.
                              • If a symbolic reference is necessary, restrict it's use to a block and relax the warning checks in block with: no strict "refs";
table of the main
                              package main;
$name = "data
package. The string can
                                                                Same as:
                                                                                                              $sref = "Pkg::var"
                                                                                                                                                         Same as:
                                                                                                             $sref->{level} = "!

                             Store a ref to a subroutine:
                                                                                                              Indirect calls:
                                                                                                              with the simpler arrow notation:
                                                                                                                                                  • $the_function->(arg1, arg2);
                                                                                                              my \$op = sub \{ my \$v1 = shift; \ my \$v2 = shift; \ return \$v1 \ ^{**} \$v2; \}; 
                              Using an anonymous subroutine, always calling it indirectly:
                                                                                                              say $op->(10, 4); # prints 10000

    Checking if a nested data struct e

                                                                                                                                                                             · It's also possible to lexically
                              Unlike most programming languages Perl automatically creates missing
Autovivification.
                              parts of arrays, hashes when an undefined value is referenced.
                                                                                                                                         exist!! See BUG section here.
                                                                                                                                                                               disable it, with the pragma:
What is autovivification?
                                                                                                                Prevent that by checking each level data in step.
                              Also see: autovivification in for loop but not assignment?
                                                                                                                                                                                  no autovivification;
Perl surprise/problem with
autovifification
                                                                                                              no autovivification 'exists': # turn it off just for exists checks. See others
                                  autovivification; # turn off vivification except for setting value
                              A closure binds its environment and keeps it to use it when invoked
                                                                                                              sub make greeting
                                                                                                                   my $greet = shift;
my $greet_fct = sub {
    my $name = shift;

  Perl closure
                                In the example at right, a greeter function is built and returned,
                                remembering how to greet. It is used like this:

my $fr = make_greeting("Bonjour");

my $it = make_greeting("Bungiorno");

$fr->('Brigitte'); # prints: "Bonjour, Brigitte!\n"

$it->('Madonna'); # prints: "Bungiorno, Madonna!\n"
  Note how easy it is to
create a closure in Perl: a
                                                                                                                         print "$greet, $name!\n";
simple block that defines
a lexical variable
                                                                                                                    return $greet_fct; } # return ref to internal function
referenced by subroutines defined in that block. The
                                                                                                                 my $count; # lexically scoped variables are only accessible inside the block sub add_1 { count += 1; } # but the subroutine is not lexical it's visible
                              A code block defining lexical variable(s) and subroutines consist of a
                                                                                                              { my $count;
variable is not accessible
                              closure too! With the following example, the add_1() subroutine
                                                                                                                            1 { count += 1; } # but the subroutine is not lexical it's visible count { return count; } # in the package (main by default).
outside of the block but
                              increments the $count and that's returned by get_count(). The
```

# The lifetime of the subroutines is the program, keeping the referred-to variables alive!

\$count variable cannot be accessed from anywhere else!

the subroutines are!

filehandles	<ul> <li>The file handle can be declared inside the statement as shown below.</li> <li>It can also be declared before, but the file handle variable must be undef when the open statement executes, otherwise open uses it as a file handle value.</li> </ul>									
Example from Grinnz:	• open my \$in_fh, '<', \$filename or die "Failed to open \$filename for reading: \$!"; • open my \$out_fh, '>>:encoding(UTF-8)', \$outfile or die "Failed to open \$outfile for appending: \$!";									
Perl 5 Built-in Functions 🚧										
Perl Functions Perl syntax	To get information about a Perl function from the command line: use the <b>perldoc -f</b> command. To get information about <b>print</b> use: <b>perldoc -f print</b> This PDF refers to several Perl built-in functions in various places.									
!Cautionary notes	Some of the Perl functions exhibit various limitations and the vary over Perl versions. This section describes the ones I am aware and the proposed alternatives.									
each keyword is broken     Use <u>Var::Pairs</u> instead.	Do NOT use the built-in <a href="mailto:each">each</a> . It is broken, as described by <a href="Damian Conway">Damian Conway</a> in his <a href="Modern Perl Best Practice O'Reilly course">Modern Perl Best Practice O'Reilly course</a> , section control structure.  • each is not re-entrant:  • nested loops of each over the same hash does not work as expected and will create infinite loop since the nested loop each juts iterates from where the first loop each left it.  • Exiting the loop leaves the state of the each internal pointer at the current location.									

· If you use each on the same hash later it will resume from where it left, it will not start form the beginning.

Perl 5 Statements 🚧									
Perl Syntax	perldoc perlsyn :Perl syntax is free-form. It borrowed concepts from many languages. See perldoc perltrap for comparisons and differences.								
Comments	Comments start with a # on a line, outside of a string or regular expressio	n.							
Statement separator	Every statement must be terminated by a semicolon, except for the last s	statement of a block where it is opti	ional. It is howeve	er customary to put it anyway.					
No semicolon after a block	A block is not followed by a semicolon. Note, however that eval {}, su but just terms inside an expression.	A block is not followed by a semicolon. Note, however that eval {}, sub {}, and do {} need explicit termination because these are not compound statements but just terms inside an expression.							
Statement modifiers	A simple statement may be followed by a single modifier just before the te	erminating semicolon:	for LIST						
! Do not use with a my state and our.	if EXPR while EXPR unless EXPR until EXPR		(Perl >= 5.14) Used in switch statement						
Compound statements	A sequence of statements inside a file, a {} delimited block, or an eval string constitute a scope.  • Because hash references are also identified by {}, it may be necessary to put a semicolon after the opening brace to identify a block. As in: {;}  • Inside all following, a BLOCK is always enclosed by braces, as in { }, even for if statements.  • In loops, the continue control statement identifies a BLOCK that is executed before the loop condition is evaluated again.								
Control flow Statements:     if/elsif/else     unless/elsif/else	if (EXPR) BLOCK if (EXPR) BLOCK else BLOCK if (EXPR) BLOCK elsif (EXPR) BLOCK if (EXPR) BLOCK elsif (EXPR) BLOCK if (EXPR) BLOCK elsif (EXPR) BLOCK else BLOCK unless (EXPR) BLOCK elsif (EXPR) BLOCK unless (EXPR) BLOCK elsif (EXPR) BLOCK else BLOCK								
while and unless loops	LABEL while (EXPR) BLOCK # run while EXPR is true LABEL while (EXPR) BLOCK continue BLOCK	LABEL until (EXPR) BLOCK LABEL until (EXPR) BLOCK							
for and foreach loops for loops foreach loops	LABEL for (EXPR; EXPR; EXPR) BLOCK LABEL for VAR (LIST) BLOCK continue BLOCK	LABEL foreach (EXPR; EXPR LABEL foreach VAR (LIST) LABEL foreach VAR (LIST)	BLOCK						
switch statement	given (EXPR) BLOCK # in <u>switch</u> statements. (Perl >= v5.14). It was	available in Perl 5.10.0 but did not	work properly un	til 5.10.1					
Iterate over multiple values at a time	LABEL for my (VAR, VAR) (LIST) BLOCK (LABEL for my (VAR, VAR) (LIST) BLOCK continue BLOCK LABEL foreach my (VAR, VAR) (LIST) BLOCK LABEL foreach my (VAR, VAR) (LIST) BLOCK continue BLOCK	Perl >= 5.36)							
Basic Blocks	A BLOCK by itself is semantically equivalent to a loop that executes once, allowing loop control keywords (see below).	LABEL BLOCK continue BLOC	rK.						

A block prefixed by the **defer** modifier provides a section of code which runs at a later time during scope exit. Requires: use feature 'refer'; (Perl >= 5.36)

**Defer blocks** 

```
Try Catch exceptions
                                     The try/catch syntax provides flow control exception handling. This
                                                                                                                                use feature 'try';
                                   syntax must be first enabled with use feature 'try';

The finally block is experimental. It cannot return, goto or use loop
                                                                                                                                      my $x = call_a_function();
$x > 0 or die "Negative not supported";
                                     controls.
                                                                                                                                      do_something_with($x);
                                   try BLOCK catch (VAR) BLOCK try BLOCK catch (VAR) BLOCK finally BLOCK
                                                                                                                                catch ($e) {
   warn "Unable to output a value; $e";
                                   The following built-in functions can be used inside the above loops.
Loop control
                                   loop control keywords:
                                                                                                The last, next, and redo loop control keywords
                                                                                                                                                                          Notes:
 Use the <u>last</u> and <u>redo</u>
                                   • <u>last</u> <u>o</u>: exits the loop.
                                                                                                                                                                          • The while and foreach loops may have a continue
                                                                                                work in the following constructs:
inside a naked block of
                                                                                                                                                                             block: executed before evaluating condition again,
                                     next o: starts the next iteration of the loop.
                                                                                                   • while (condition) { ... }
code to control looping.
                                                                                                                                                                              which corresponds to the 3rd part of a for loop
                                      redo o: restarts the loop block without
                                                                                                   • until (condition) { ... }
                                                                                                                                                                              statement. See this @ stackOverflow.
                                      evaluating the condition again.
                                                                                                   • for (init; condition; continue) { ... }

    Blocks can be labelled <u>o</u> as targets to <u>last</u>, <u>next</u>,

                                                                                                   • foreach array \{ \dots \}
                                                                                                                                                                             and redo
                                                                                                   • naked block: { ... }
Specially Named Blocks
PHASE BLOCK
                                   5 specially named blocks are run at the various phase of a running program: BEGIN, UNITCHECK, CHECK, INIT and END.

See: <u>BEGIN block - running code during compilation</u>. Note the <u>security risk warnings</u>. The <u>BEGIN block is used to implement other Perl functionality</u>.
                                     if EXPR
                                                                          The for and foreach statements impose a list context; the complete list is The while statement imposes a scalar context; it takes
Statement modifiers
                                      unless EXPR
while EXPR
                                                                          processed. Therefore a loop like the following trying to stop on a line that has "_END_" on it will not work since it reads all of STDIN:
                                                                                                                                                                          one line at a time from <STDIN> and the following code
                                                                                                                                                                          works properly:
                                                                                      foreach (<STDIN>) {
  last if ?_END_/;
                                      until FXPR
                                                                                                                                                                                         while (<STDIN>) {
                                                                                                                                                                                            last if /_END__/;
                                      for LIST
                                      foreach LIST
                                                                                       ...;
}
                                                                                                                                                                                            ...;
                                   • The do block is *very useful* to set a value based on several
                                                                                                                               my next step = do {
do block
                                                                                                                                  y $next_step = 00 {
    my ($perl_nirvana, $emacs_nirvana) = check-nirvana-levels();
    if ($perl_nirvana < 5 && $emacs_nirvana < 8) { 'study-Perl' }
    elsif ( some_other_cond() ) { 'time-to-cook' }
    elsif ( $emacs_nirvana < 7 ) { 'look-into-eieio' }
    else { $isit_winter? 'go-skiing' : 'go-canoeing' }</pre>
                                      conditions, just as the ?: conditional operator but with an explicit block that may use scoped variables.
                                     Takes advantage of a block value is the value of the last expression executed inside the block. Do *not* return from the block.
                                     The last, next and redo cannot be used inside do blocks.
                                     The do blocks are not semantically equivalent to loop blocks.
                                   Perl supports 3 forms of goto statements: goto-LABEL, goto-EXPR, and goto-&NAME. Note that loops labels cannot be used.
goto statement
```

#### Perl 5 Subroutines ###

Perl subroutines Object Oriented Perl, 2.1.4	<ul> <li>Parentheses are optional when calling a subroutine. In some cases, using them prevents mis-interpretations.</li> <li>Also note that blocks are often passed as first argument to a subroutine.</li> </ul>							
Declaring subroutine In all cases, it's less	Declare a subroutine to use as a list operator.     use or or not     because it binds too tightly.	<pre>sub seed_for; \$val = seed_for \$0 or die 'seed_for failed';</pre>						
ambiguous to define the subroutine before use and use parentheses in calls.	Declare a subroutine to use as a unary operator:	<pre>sub seed_for(\$); # use subroutine prototype to dec \$val = seef_for \$0    die 'seed_for failed</pre>						
Defining subroutine	Defined with the <u>sub</u> keyword followed by a block.	sub greet { print "hello!\n"; }						
Calling a subroutine	If the subroutine definition follows its invocation, parentheses after the subroutine name are required, as in: greet();	But if the definition was above the call, the parentheses     Subroutine sigil is &. It can optionally be used in a call;						
pass current @_array	Call with & prefix without args, as in ⊂_function; to pass current @	array. Used to call a helper subroutine with in the primary	one, providing all its arguments.					
• goto	From a subroutine use goto ⊂_function; to transfer control to that su	ubroutine instead of calling it. It also passes the current @_	array to it.					
calling a method	Parentheses are required if arguments are passed to method, but optional if there is no arguments.	<pre>\$obj-&gt;method_with_args(\$val1, \$valb); \$obj-&gt;method_without_arg; \$obj-</pre>	>method_without_args();					
subroutine &	Why we teach the subroutine ampersand     Why should I use the & to call a Perl subroutine? @ StackOverflow	Another point of view: <u>Subroutines and Ampersands</u> Note it must be used to <u>make a reference</u> to a subroutines.	ne: \$greeter = <b>\&amp;</b> greet;					
<ul><li>subroutine arguments</li><li>passed by list</li><li>always variable by</li></ul>	The arguments passed to a subroutine are available to its code via the special <code>@_</code> array.  The caller code supplies a list of values. Lists lists are flattened in Perl.	@sorted = alpha_order('Nice', 'Québec', 'Montréal'); @sorted = number_order @unsorted_numbers; @sorted = alpha_order('Trois-Rivières', @sorted, 'Gaspé', 'Rimouski');						
nature • named arguments Note: The @_ is an alias to the passed values; changing them inside the subroutine affects the caller's values.	Since hash declaration take a list of key/value pairs, it's easy to implement a passing named arguments! It's also possible for the subroutine to set defaults for some of the expected arguments by taking advantage of the fact that hash are lists, list are flattened and hash can be assigned a list with the last values are used.	<pre>Implementation: sub move { my (%directions) = @_; } Caller: move(up=&gt;3, left=&gt;4); move('down', 2); # it's by convention! To set a default: sub move {   %default = (up=&gt;0, down=0, left=&gt;0, right=&gt;0);   my (%directions) = (%default, @_);   }</pre>						
Subroutine Prototypes	An older Perl feature. Clashes with subroutine signatures as of Perl v5.20.	In $Perl >= v5.20$ put the <b>:prototype</b> attribute before sub	proutine prototype parenthesis.					
Subroutine signatures	Exactly zero arguments ()	Zero or 1 argument, no default, unnamed:	(\$=)					
<ul><li>Perl &gt;=5.36: Stable</li><li>Perl &gt;= 5.20:</li></ul>	Zero or 1 argument, no default, named (\$val=)	Zero or 1 argument, named, with default	(\$val=1)					
Experimental See: <u>Use v5.20</u>	exactly 1 named argument: (\$val)	Exactly 2 arguments	(\$v1, \$v2)					
subroutine signatures	2, 3 or 4 arguments no defaults: (\$v1, \$v2, \$=, \$=)	2,3 or 4 arguments, 1 default:	(\$v1, \$v2, \$v3='a', \$=)					
	Two or more, any number of arguments. (\$v1, \$v2, @)	Two or more arguments, remainders into a named array:	(\$v1, \$v2, @rest)					
	Two or more arguments: an even number (\$v1, \$v2, %)	Two or more arguments, remainders into a named hash:	(\$v1, \$v2, %rest)					
	Class method (\$class,)	Object method	( \$self,)					
Returned value.  Detecting calling context with wantarray	<ul> <li>The result of the last evaluated expression is implicitly returned.</li> <li>The <u>return</u> operator can be used but it's not required unless used to ch</li> <li>The subroutine can return a scalar in scalar context or a list if called in I</li> <li>Inside the subroutine, use the <u>wantarray</u> function to determine the c</li> </ul>	list context.	,					
Identify <u>caller</u>	The caller built-in returns information about the subroutine caller inside a	n array: ( package, file_name, file_line). In scalar context it re	eturns the package only.					
AutoLoading	On a call to undefined subroutine Perl checks if the package defines an \$AUTOLOAD subroutine it calls that.  Also see: AutoLoader.							

#### Perl 5 Classes, Objects and Methods

The goto built-in can be used by a subroutine to continue its execution into another subroutine. Not for all but useful in some specific cases such as autoloading.

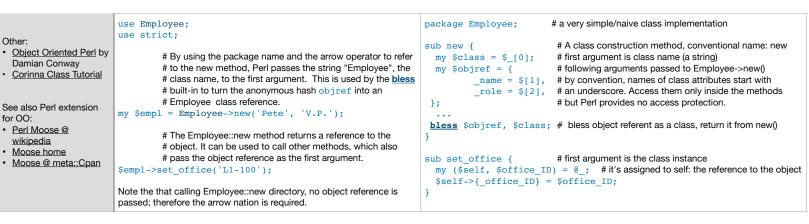

**Object Oriented Perl** To build a Perl class with common Perl: 1) create a package with the name of the class inside a module, 2) write functions in the package. 3) bless a referent. Perl OO Tutorial By convention, something a name that starts with an underscore is internal, not meant to be used directly. Perl Module Library There is nothing preventing direct access, but users of the class should not access it directly (as OO design principles recommend). Module creation Perl ignore prototypes of methods.
It's possible to create class methods and class attributes: Their scope must be the scope of the module they are defined in.

Perl ignore prototypes of methods and class attributes: Their scope must be the scope of the module they are defined in. guideline

Destructors are normally not required, as Perl automatically destroys objects at their end-of-life based on scope. It's needed when classes use circular references.

Continuation with goto

It is possible to create explicit destructor by defining a DESTROY method in the class. See The destructor called DESTROY and Object Oriented Perl book.

Opening Files	All file open operations are relative to the <u>current working</u> relative file names)	ng directory (for	open my \$filehandle, '<	<pre>&lt;:utf8', 'a_relative/path.txt'</pre>		
Creating temporary files	File::Temp (Perl >= v5.6.1). <u>Using File::Temp</u> . Also see	!O::File				
<b>Built-in Functions</b>	Related Functions/Packages / Descriptions			Notes		
Getting file names by:  • Globbing:  • with glob	File::Glob (Perl >= v5.6.0) - provides more control.	Example:	<pre>my @all_files = glob ' my @perl_files = glob '</pre>	*'; '*.pm *.pl';  # 2 globs, space-separated		
with the glob     operator <>	The <> operator is identifying:     a filehandle, when: the item inside <> is a Perl identifier or an indirect file handle read scalar,     a glob expression otherwise.	Glob examples:		# 1 glob: no space, no need for string n *.pl'>; # 2 globs, space-separated		
.,			<pre>my \$etc_dir = '/etc'; my @etc_dir_files = &lt;\$e</pre>	etc_dir/* \$etc_dir/.*>;		
			my @files = <larry *="">;</larry>	# a glob		
	See: <u>readline</u>	Filehandle examples:		>; # indirect filehandle read of LARRY handle ine LARRY; # another way to write above		
with a directory handle     LPo	opendir: open a directory: get a directory handle     readdir: read the directory handle. But see this.     closedir: close the directory handle.     DirHandle (Perl <= 5.5)     File::Spec::Functions (Perl >= v5.5.4)     Path::Class	Example: iterate explicitly over a list of file names extracted from the directory using these 3 functions.	<pre>opendir my \$dh, \$dir or die "Failed opening \$dir: \$!";</pre>			
Creating directory	• mkdir	Example:	<pre>mkdir \$dir_name, oct(\$permissions); # octal for permissions mkdir \$dir_name, 0700; # do not use "0700", it's 700 decimal</pre>			
Removing directory	rmdir Removes an empty directory.     File::Path remove_tree_, rmtree_remove_dir & files (limits).	Perl >= v5.0.1)				
Removing files	• <u>unlink</u> a list or <u>\$</u>		unlink 'file1.txt', 'fi unlink qw( file1.txt fi unlink glob 'file?.txt'	ile2.txt);		
Renaming files	rename an old file name to a new one.     The fat comma operator is sometimes used to highlight what is the old and the new name.	As in here:	rename 'old_name' , 'ne rename old_name => 'ne	ew_name'; ew_name'; # use fat comma to quote word left of it.		
Changing permissions	chmod changes file permissions					
Changing ownership	• <u>chown</u> changes file ownership					
Creating Hard link	link to create a hard link					
Creating symbolic link	symlink to create a symbolic link					
chdir Change current working directory	File::chdir     File::HomeDir	• chdir without \$ENV{LOGDIR	urrent working directory.  It argument attempt to change to user home directory using the \$ENV{HOME} and  It argument values if  they are set. The File::HomeDir module helps in setting them.  It is global for the entire program. Use File::chdir facilities for localized operations.			
Modules	Functions Legend: Exported by default, exported on request, W	in32 specific		Extra Information		
Cwd	getcwd, cwd, fastcwd, fastgetcwd, getdcwd     abs path, realpath, fast abs path			<pre>use Cwd; my \$curdir = getcwd; print "cwd is \$curdir\n";</pre>		
File::Basename	fileparse, basename, dirname,					
File::Spec File::Spec::Functions	functional interface to methods: canonpath, catdir, splitpath, splitdir, catpath, abs2rel, rel2abs. All can be	catfile, curdir, roc be imported by using	otdir, updir, no upwards, file naming the :ALL tag.	ne is absolute, path. devnul, tmpdir, case tolerant,		
File::Find : Traverse a directory tree. See: File::Find::Closures	find, finddepth, %options. In wanted: File::Find::dir, Note that \$_gets the base name of the file (no path). It perform filetest operations in the example here (as expl-s, and implicit argument to -d and -f). This traverses the find find file file for the file (as expl-s) and implicit argument to -d and -f).	is used to licit argument to	use File::Find;			

### Topic: List Operations

				<u> </u>	- ' '			
List Operators								
Sorting lists	sort	Sort a list		my @sorted = sort @u	nsorted_list;	in place:	my @data = <u>sort</u> @data;	
	reverse	Sort a list in revers	e order	my @rsorted = revers	e @unsorted_list;	in place:	my @data = <u>reverse</u> @data;	
Filtering list with grep	my @adult_ages = grep \$_ > 18, @ages;			$ \label{eq:my_elucky_ages} \mbox{ my @lucky_ages} = \mbox{ $grep } \mbox{ / $\$, >= 7 \& \$_ <= 77  @ages = \mbox{ $grep }   $				
Counting matches	my \$count = <b>grep</b> \$_ > 18, @ages;							
		An expression, subroutine or block with trailing boolean can be used as the grep criteria. Each item in the list is identified inside grep by \$_ The block is an anonymous subroutine.						
Transform a list with map	map bloo     map EXF			LOCK or EPR for each elements a list with the results.	ent of LIST, setting \$_ to each		can generate a single value, a list or 0 or s. The result list flattened anyway.	

## Topic: Process control

<b>Process Control</b>	In Books: LPo Important security information: peridoc perisec					
<b>Environment Variables</b>	Inside the <u>%ENV</u> hash.	Perl %Config hash: Perl configuration information. For example, whether it support threads, what are path separators, etc  • To use it: use Config;				
Built-in Functions	Example	Description/ Notes				
• using the shell • security risk?	<pre>system 'ls -1 \$HOME';</pre>		Run child process asynchronously using parent's stdin, stdout and stderr, using the OS native command shell.			
	<pre>system "cd \$project; make &amp;";</pre>		Use the Unix shell to execute a long running build asynchronously.   However: avoid using the shell like this.  Using the shell to build commands from unvalidated user input data may lead to security issues.			
avoiding the shell	system 'tar', 'cvf', \$tarfile, @directories;		No shell invoked when more than 1 argument is passed to system. No shell interpretation, piping, re-direction done.			
other syntax	system( 'tar', @arguments);		O means success: unless (system 'tar', arguments) { print "tar command success\n"; }			
	system( { \$prog }, \$arg0, @a	args);				
	Note that if the string contain <b>no</b> shell <b>metacharacters</b> it is executed directly (not through a shell).					

system return value:	2 bytes:	MSByte: child prog	gram exit code.	my \$retval = syst	<u>tem</u> ( );			
<ul> <li>A value of 0 usually means all was OK.</li> </ul>		LSByte: system-sp	pecific	my \$childp exited	ode = \$retwa	1 >> 8.	← shift most significant byte	
		information bits: • 0x80 : set on co	are dumn	my \$had_core_dum		ral & 0x80) == 0x80? 1 : 0;	← use least significant byte	
		• 0x7f : <u>signal</u> nu		my signal_number	= \$retv	al & 0x7f;		
exec	Unlike syst	Unlike system, exec does not return to the parent Perl process. Use: exec 'the_program' or die "Could not run: \$!"; #or warn or exit						
backquotes``	Use backquotes to <b>capture the stdout</b> of a program. That's the main point of using it.  • The trailing newline is not filtered out; it can be filter by <b>chomp</b> .						nt_date = `date` );	
	<ul> <li>The value inside the backquotes is treated like the single double quote string argument of system: it will invoke the shell if there are any shell meta-characters and supports interpolation.</li> <li>The following example builds a dictionary (hash) of topics with the text extracted from perldoc.</li> <li>Note that `` is also written as qx/ /</li> <li>backquote operation in scalar context returns 1 string. In list context it returns a list of strings (1 per line).</li> </ul>						. {	
Modules								
Capture streams	Capture:	• Capture::Tiny  Can be used to capture the stdout and stderr streams for various ways if executing other programs						
Inter-process support	Can also be used to capture streams and provide more inter-process support.     It provides systemx which never uses the shell, along with other useful functions.							
Processes as filehandles	In Books: L	In Books: <u>LPo</u>						
Perl + program		a process that	open DATE, 'dat	te   or die "Cannot pipe fr	rom date: \$!";	Use a bare word to de	fine the DATE file handle.	
	pipes into the Perl process	open my \$date_fh, '- ', 'date' or die "Cannot pipe from date: \$!";		This one and the others define a local file handle variable. The file handle variable can later be used to read, as the above one, but is not global.				
			open my \$ps_fh, '- ', 'ps', 'aux' or die "Cannot pipe from ps: \$!";					
			open my \$find_fh, '- ', 'find', qw(name '*.p[lm]' -print ) or die "Cannot pipe from find: \$!";					
Perl ➡ program	Launching a process that the Perl process pipes into.  open my \$dispather_fh, ' -', 'dispatcher', qw ( '-to-perl-groups' 'Help!' ) or die "Cannot pipe to the dispatcher: \$!";							
<u>Forking</u>	In Books: L	<u>.Pσ</u> . See also: Linu	ux <u>fork(2)</u> system	call, QA: Why do we nee	d fort to create ne	ew processes? Why fork woks the way it	does?	
fork with	• fork the process into defined(my \$process_id = <u>fork</u> ) or die "Fork failed: \$!";							
exec and waitpid	parent ar	nd child. ild process start	<pre>unless (\$process_id) {     # Inside the child process (created by fork)     exec 'long_running_process' or die "Failed starting long_running_process: \$!";</pre>					
See also:	the progr	ram with exec						
<ul><li>Other IPC functions</li><li>Perl IPC</li></ul>	• In the parent process wait for the program termination with waitpid  • In the parent process wait for completion of long_running_process.  waitpid(\$process_id, 0);							
<u>Signals</u>	In Books: L							
<u>kill</u>	Sends a signal to a list of processes.  • The signal may be identified by number or name (string), which is more portable.  • The \$Config{sign_name}\$ provides the supported signal names.					with SIGINT: \$!";		
	e that the fat comma operator (=>) can be used to automatically quote signal name:				kill INT => \$pid or die "Can't signal \$pic	d with SIGINT: \$!";		
	If the signal is 0 or "ZERO" no signal is sent to the process; instead Perl checks if it's possible to send a signal to the process: ie: if the process exists.				unless (kill 0, \$process_id) {  warn "Process \$process_id is no longer }	er running!";		
		nal is a negative nur group identified by t		hat starts with '-' the signa ar argument.	al is sent to the	• <u>kill</u> '-KILL', \$process_group • <u>kill</u> -9, \$process_group		
Signal handlers	Set the signal handler by setting <code>%SIG</code> for the signal name (with no 'SIG' prefix) to a string holding the name of the subroutine.					<pre>\$\sig('INT') = 'dispatcher_int_</pre>	_handler';	
Error Logging and Reporting	<ul> <li>Perl supports the warn buil-in to generate warnings on stderr.</li> <li>The <u>Carp::carp</u> from the <u>Carp</u> package, provides more information.</li> </ul> • Log::log4perl is an implementation of the popular Apache <u>Log4j</u> for Perl.							
i .								

# PerlTidy formatting control

perItidy option	Option	Impact
indentation style	-bl,    opening-brace-on-new-line    brace-left	<ul> <li>Without this option (the default) the code indentation style selected is <u>K&amp;R style</u>.</li> <li>With this option, the indentation style is <u>Allman/BSD style</u>.</li> </ul>
