Perl scripts

Wilding Fell scripts	impose strictures in Ferrilles t	e strictures in Peri files to prevent errors by adding one of the following use lines. Also see the strictures package.		
Use the following at the beginning of Perl script files. perldiag @ perldoc	<pre>#!/usr/bin/perl use strict; use warnings; use diagnostics;</pre>	<pre>#!/usr/bin/perl -w use v5.12; # loads strict</pre>	 The first line of an executable script should be a valid <u>shebang line</u> identifying the appropriate location of the Perl interpreter. Most Perl code should also activate the strict Perl rules and warnings to detect warnings. See: <u>Barewords in Perl</u> use <u>diagnostics</u>; line to produce more diagnostics for detected warning or errors. 	
use version/features	<u>use</u> v5.36;	This can be used to enable both the strict and warning pramas as well as several <u>named features</u> . • See the <u>table listing the feature bundles per Perl versions</u> .		

Perl 5 Operators

```
Perl has a large number of operators, listed below with their precedence and associativity.
Perl 5 Operators
                               C Operators missing from Perl: unary &, unary * and (type)

Quote and Quote-like operators: in Perl quotes are operators and they provide various kind of interpolating and pattern matching capabilities.
                   Note:
Associativity: one of:
                             left
                                          terms and list operators (leftward)
  right
                             left
                                          Arrow Operator:

    left

                             NA
                                          Auto-increment and Auto-decrement:
                                                                                       ++ --
• NA : not associative:
                             right
                                          Exponentiation:
  cannot use more than
                                                                                      ! ~
                             right
                                          Symbolic Unary Operators:
                                                                                               -. \ and unary + and -
                                                                                                                                           Note: The operator \ <u>creates a reference</u>. See <u>example</u>.
  one of these operators
                             left
                                                                                       =- !-
                                          Binding operators:
  in sequence.
                             left
                                          Multiplicative Operators:
                                                                                      * / % x
· CH: chained
                             left
                                          Additive Operators:
                             left
                                                                                              >>
                                                                                       <<
                                          Shift Operators:
                             NA
                                          named unary operators
To get this information,
                             NA
                                           Class instance Operator:
                                                                                      isa
                             СН
                                                                                      as numbers: < >
                                                                                                                                as strings: 1t
peridoc periop
                                          Relational Operators:
                                                                                                                                                      qt
                                                                                                                                                             le
                                                                                                                                                                      qe
                             CH/NA
                                                                                      as numbers: == !=
                                          Equality Operators:
                                                                                                                                as strings: eq
                                                                                                                                                      ne
                                                                                                                                                              cmp
                             left.
                                          Bitwise And:
                                                                                          &.
                                                                                      &
                             left
                                          Bitwise Or and Exclusive Or:
                                                                                          1.
                             left
                                          C-style Logical And:
                             left.
                                           Logical Defined-Or:
                                                                                      П
                                                                                                 //
                             NA
                                          Range Operators:
                             right
                                          Conditional Operator:
                                                                                      ?:
                             right
                                           Assignment Operators:
                                                                                                           /=
%=
                                                                                                           x=
                                                                                      goto last next redo dump
                             1eft
                                          Comma, fat-comma Operators:
                                                                                    . =>
                             NA
                                          list operators (rightward)
                             right
                                                                                    not
                             left.
                                          Logical And:
                                                                                    and
                             left
                                          Logical or and Exclusive or:
                                                                                    or xor
                                          Converts a string that starts with digits into a number.
                                                                                                             print -+- '22les poulets!';
trick operators
                             -+-
                                                                                                                                                        -+- is essentially - + - or - - but a + to allow placing
                                                                                                             # prints 22
These are not real Perl
                             0+
                                                                                                                                                        them together. The 0+ does the same as -+-, but
operators, but look like
                                                                                                                                                        the second has higher precedence.
operators: they are
                                          Called the 'goatse' operator. It causes the right side expression to be evaluated in array context. Used to assign
                                                                                                             my $str = "A 22 before 33 does not make 9, it is 44!";
                             =()=
concatenation of other
                                                                                                            my $digit_count =()= $str =~
print "$digit_count";
operators that achieve a
                                                                                                                                                      /\d/q;
                                          the array/list size to a scalar.
                                                                                                                                                      # prints '7',the number of digits in $str
specific effect.
See the link for others.
                                          Useful to interpolate an array inside a string.
                                                                                                             print "these people @{[get_names()]} get promoted"
                             @{[]}
Understanding these
                                          Note that: "@{[something]}" is the same as join $", something
operators helps
understand Perl. They
should not be used in
                                          Force scalar context.
                                                                                  In scalar context localtime() returns human readable time,
                                                                                                                                                        $ perl -le 'print ~~localtime'
                                                                                                                                                        Mon Nov 30 09:06:13 2009
                                                                                  but in list context it returns a 9-tuple with various date
                                                                                  elements.
Truth and falsehood
                             • False in a boolean
                                                                 Negation of a true value by "!" or "not"
                                                                                                            So the following scalar values are
                                                                                                                                                        All other scalar values, including the following are
                                                                 returns a special false value.
When evaluated as a string it is treated as ", but as a number, it is
                                                                                                            considered false:

• undef - the undefined value
                                context.
                                                                                                                                                        true:
                                                                                                                                                          1 any non-0 number
' ' the string with a space in it
                                • the number 0,
1. Remember that the
                                                                                                             • 0 the number 0, even if you write it
                                • the strings '0' and
strings '0' and " mean false. The output of
                                                                  treated as 0.

    '00' two or more 0 characters in a string

                                                                                                               as 000 or 0.0
                                • the empty list (),
                                                                                                                the empty string.
                                  "undef
                                                                                                                                                          "0\n" a 0 followed by a newline
glob() may return a file named '0'!
                                                                                                             • '0', a single 0 in the string.

    All other values are true.

    'false' . Even the string 'false' evaluates to true.

 ! a bareword false has

    one way to define valid true and false constant symbols that can be used in assignments (but see ←):

                                                                                                                                                use constant { true => 1. false => 0 }:
a truth value of true!!!
                                                                                                                                                     (-e $fname && -f
File test operators
                             It is possible to combine the file test operator with the AND operator as in the following example:
                                                                                                                                                                               && -r
                                                                                                                                                  print("$fname exists, is readable\n"); }
                                          is readable
The most important
                                                                                         exists.
                                                                                                                                                        is a block special file.
                                                                                                                                                        is a character special file.
operators are shown
                              -w
                                          is writable
                                                                                  -z
                                                                                         is empty
                                                                                                                                                  -c
                                                                                                                                                        handle is opened to a tty. has setuid bit set.
                                          is executable
                                                                                         has nonzero size (returns size in bytes).
They check if the file...
                                          is owned by effective uid.
                                                                                         is a plain file.
                             -o
-R
-W
-X

Input/Output Layers. Internal use by PerlIO only.	\${^OPEN}			Unicode Settings of Perl	\${^UNICODE}	
Internal UTF-8 offset caching code state	\${^UTF8CACHE}			State of UTF-8 locale detected by perl at startup.	\${^UTF8LOCALE}	
File handle Variables	See also: Perl File Handles		The following variables	are used in the Input/Output handling as well as program arguments.		
Name of current file read from <>	\$ARGV		arguments of the script nd operator <>. ➡	@ARGV	Number of arguments minus one	\$#ARGV
Special file handle that iterates over command-line filenames in @ARGV	ARGV	Special file hand currently open o edit-in-place pro	utput file when doing	ARGVOUT		
Output field separator for the print operator	 IO::Handle->output_field_separator(EXPR) \$OUTPUT_FIELD_SEPARATOR \$OFS \$, 			Current line number for the last file handled accessed	HANDLE->input_\$INPUT_LINE_N\$NR\$.	line_number(EXPR) UMBER
Input record separator (newline by default)	 IO::Handle->input_record_separator(EXPR) \$INPUT_RECORD_SEPARATOR \$RS \$/ 			Output record separator	 IO::Handle->output_record_separator(EXPR) \$OUTPUT_RECORD_SEPARATOR \$ORS \$\\ 	
Auto-flush control order of output @ Perl Maven Suffering from Buffering?	HANDLE->autoflush(EX SOUTPUT_AUTOFLUSH \$I	TPR)	Perl activates file buffering by default. Assign 1 to \$ to activate auto-flush.	Last read file handle	\${^LAST_FH}	
Perl 5 Input/Output						

Perl 5 Input/Output

Perl 5 Statements

Loop control	See <u>perlsyn</u> for more information on Perl syntax	which includes declarations, blocks, loops, labels, subrout	ines, etc
Use the <u>last</u> and <u>redo</u> inside a naked block of code to control looping.	loop control keywords: last g: exits the loop. next g: starts the next iteration of the loop. redo g: restarts the loop block without evaluating the condition again.	The last , next, and red loop control keywords work in the following constructs: • while (condition) { } • until (condition) { } • for (init; condition; continue) { } • foreach array { } • naked block: { }	Notes: • The while and foreach loops may have a continue block: executed before evaluating condition again, which corresponds to the 3rd part of a for loop statement. See this @ stackOverflow. • Blocks can be labelled g as targets to last, next, and redo

Statement modifiers	• if EXPR • unless EXPR • while EXPR • until EXPR • for LIST • foreach LIST • when EXPR • do block	The for and foreach statements impose a list context; the complete list is processed. Therefore a loop like the following trying to stop on a line that has "_END_" on it will not work since it reads all of STDIN: foreach (<stdin>) { last if ?_END/; ; }</stdin>	The while statement imposes a scalar context; it takes one line at a time from <stdin> and the following code works properly: while (<stdin>) { last if /_END/; ; }</stdin></stdin>
Conditional statements			

Perl 5 Subroutines

Perl subroutines				
subroutine &	Why we teach the subroutine ampersand Why should I use the & to call a Perl subroutine	ne? @ StackOverflow	Another point of view: Subroutines and Ampersands	
Subroutine Prototypes	An older Perl feature. Clashes with subroutine sign	gnatures as of Perl v5.20). In Perl >= v5.20 put the :prototype attribute before sul	broutine prototype parenthesis.
Subroutine signatures	Exactly zero arguments	()	Zero or 1 argument, no default, unnamed:	(\$=)
Perl >= 5.36: Stable Perl >= 5.20: Experimental See: Use v5.20 subroutine signatures	Zero or 1 argument, no default, named	(\$val=)	Zero or 1 argument, named, with default	(\$val=1)
	exactly 1 named argument:	(\$val)	Exactly 2 arguments	(\$v1, \$v2)
	2, 3 or 4 arguments no defaults: (\$v1,	\$v2, \$=, \$=)	2,3 or 4 arguments, 1 default:	(\$v1, \$v2, \$v3='a', \$=)
	Two or more, any number of arguments.	(\$v1, \$v2, @)	Two or more arguments, remainders into a named array:	(\$v1, \$v2, @rest)
	Two or more arguments: an even number	(\$v1, \$v2, %)	Two or more arguments, remainders into a named hash:	(\$v1, \$v2, %rest)
	Class method	(\$class,)	Object method	(\$self,)
Variables in subroutines	global by default			
	my local, lexical scope, non persistent			
	state Local, lexical scope, persistent	Perl >= v5.10	Restriction: in Perl < v5.28: array and hashes state cannot	be initialized in list context.
	our creates a lexical scoped alias to a p	ackage variable		
	local			
Returned value	The result of the last evaluated expression is i The return operator can be used but it's not re The subroutine can return a scalar in scalar co Inside the subroutine, use the wantarray fu	equired unless used to chontext or a list if called in		e).

Perl 5 Built-in Functions

Perl Functions Perl syntax	 To get information about a Perl function from the command line use the perldoc -f command. To get information about print use: perldoc -f print
! Cautionary notes	
 each keyword is broken Use <u>Var::Pairs</u> instead. 	Do NOT use the built-in each. It is broken, as described by <u>Damian Conway</u> in his <u>Modern Perl Best Practice O'Reilly course</u> , section control structure. • each is not re-entrant: • nested loops of each over the same hash does not work as expected and will create infinite loop since the nested loop each juts iterates from where the first loop each left it. • Exiting the loop leaves the state of the each internal pointer at the current location. • If you use each on the same hash later it will resume from where it left, it will not start form the beginning.

Perl 5 Modules **##**

Perl Modules	Modules					
Perl core modules	• How to o	How to detect where a module is installed: perldoc -1 Module				
Modules @perltutorial Modules		Looks for the module file by searching the @INC path. • If Perl finds the file, it places the code inside the calling program and executes it. Otherwise, Perl will skip the do statement silently.				
Using simple modules <u>or</u>	require	Loads the module file once. • If the require for the same file appears twice, Perl ignores it. Perl will issue an error message if it cannot find the file.				
	use	Similar to require except that Perl applies it before the program starts. • Therefore the use statement cannot be invoked inside conditional statements such as if-else. Used often to include a module in a program.				

PerlTidy formatting control

perItidy option	Option	Impact
indentation style	bl,opening-brace-on-new-linebrace-left	 Without this option (the default) the code indentation style selected is <u>K&R style</u>. With this option, the indentation style is <u>Allman/BSD style</u>.
