Perl scripts

Writing Perl scripts	Impose strictures in Perl files to prevent errors by adding one of the following use lines. Also see the strictures package.							
Use the following at the beginning of Perl script files. perldiag @ perldoc	<pre>#!/usr/bin/env perl use strict; use warnings; # for testing only: use diagnostics;</pre>	#!/usr/bin/perl -w use v5.12; # loads strict use v5.35; # &loads warnings It's best to: use warnings; perl -w generates warning for all Perl code in the program including modules used by the program. Also use the _c option to check syntax. Maternative: perl -M diagnostics . Emacs pel-perl-critic command can report diagnostic.						
use version/features	<u>use</u> v5.36;	This can be used to enable both the strict and warning pramas as well as several <u>named features</u> . • See the <u>table listing the feature bundles per Perl versions</u> .

Perl 5 Operators
Perl 5 Operators
                             Perl operators, listed below with their precedence and associativity.
                                                                                                                                            C Operators missing from Perl: unary &, unary * and (type)

    Quote and Quote-like operators: in Perl quotes are operators and they provide various kind of interpolating and pattern matching capabilities.

                   Note:
Associativity: one of:
                             left
                                          terms and list operators (leftward)
                                                                                                                                        Note: print, sort, reverse, chmod, are list operators
  right
                             1eft
                                          Arrow Operator:
  left
                             NA
                                          Auto-increment and Auto-decrement: ++ --
• NA : not associative:
                             right
                                          Exponentiation:
  cannot use more than one of these operators
                             right
                                          Symbolic Unary Operators:
                                                                                     1 ~
                                                                                           -. \ and unary + and -
                                                                                                                                        Note: The operator \ creates a reference. See example.
                             left
                                          Binding operators:
   in sequence.
                             left
                                                                                    * /
                                                                                           %
                                          Multiplicative Operators:
                                                                                                  x

    CH: chained

                             left.
                                          Additive Operators:
                             left
                                                                                           >>
                                         Shift Operators:
                                                                                     <<
                             NA
                                          named unary operators

                                                                                In scalar context localtime returns human readable time.
operators that achieve a
                                                                                                                                                     $ perl -le 'print ~~localtime'
                                                                                but in list context it returns a 9-tuple with date elements.
                                                                                                                                                       on Nov 30 09:06:13 2009
specific effect.

    Negation of a true value by "!" or "not"

Truth and falsehood
                             False in a boolean context:
                                                                                                          These scalar values are false:
                                                                                                                                                     All other scalar values are true, such as:
                                                                returns a special false value.

When evaluated as a string it is
                                                                                                            undef - the undefined value
                                                                                                                                                       1 and any non-0 number
                               • the number \mathbf{0},
 1 The strings '0' and '
                               • the strings '0' and ' '.

    0 the number 0, even if you write it

                                                                                                                                                         ' the string with a space in it
mean false. The output
                                                                treated as ", but as a number, it is treated as 0.
                                                                                                                                                     • '00' two or more 0 characters in a string
                                                                                                             as 000 or 0.0
                                  the empty list ().
of glob() may return a file

"0\n" a 0 followed by a newline
'true'. 'false' . Even 'false' evaluates to true.

                                                                                                              the empty string.
                                  "undef
named '0'!
                                                                                                          • '0', a single 0 in the string.
 1 The bareword false
                              All other values are true.
                                                                                                                                              use constant { true => 1, false => 0 };
 has a truth value of true!
                             🤞 One way to define valid true and false constant symbols that can be used in assignments (but see 🗢):
                                                                                                                                               if (-e $fname && -f _ && -r _
                                                                                                                                               if (-e $fname && -f _ && -r _ ) {
  print("$fname exists, is readable\n"); }
File test operators
                             File tests can be stacked (-r -w -e $fname) or combined as in the following example or:
See filetest -X
                               Notice the underscore in the example: it's the virtual filehandle _ accessing the last stat or lstat result :
                                         is readable by effective uid/gid
                                                                                                                                                     is a block special file.
The operators check if
                                                                                       exists.
                                         is writable by effective uid/gid is executable by effective uid/gid
the file..
                                                                                       is empty
                                                                                                                                                     is a character special file.

                                                                                              Examples:
                                                                                                             \underline{my} @values = (42, 36, 99); \underline{my} ($v1, $v2) = (42, 36);
Scope of variables in Perl
                               state
                                                                                              Perl >= v5.10
                                                                                                                 Restriction: in Perl < v5.28: array and hashes state cannot be initialized in list context.
                                            Local, lexical scope, persistent
@Perl Maven
                               <u>our</u>
                                            Creates a lexical scoped alias to a package variable
                                             Localizes an existing package variable to the current scope. It's not a declaration. The variable previous value is restored when leaving the scope.
                               local

The <u>local</u> keyword was used to achieve localized variables before my variables existed, but it should no longer be used that way.
It should be used to localize modifications to a global variable or hash value.

Perl types
                           $
                               $foo
                                                      Simple scalar value
                                                                                                                    $#days
                                                                                                                                          Last index of array @days.
Scalar
                               $days[28]
                                                      29th element of array @days
                                                                                                                    $days->[28]
                                                                                                                                          29th element of array pointed to by reference $days.
                                                      Value associated with the Feb key of hash %days
                                                                                                                                          Multi-dimensional array
                               $days{'Feb'}
                                                                                                                   $days[0][2]
                                                                                                                   $d{99}{'Feb'}
$d{99, 'Feb'}
Archaic use of single
                               ${days}
                                                      Same as $days, use before alphanumumerics.
                                                                                                                                          Multi-dimensional hash
quote:
                                                      The $days variable inside the Dog package.
                                                                                                                                          Multi-dimensional hash emulation
             $Dog'days
                               $Dog::days
                                                                                       • You can assign a list of values to a list of variables. Useful to swap: ($val1, $val2) = ($val2, $val1);
list and Array
                               · Arrays are initialized by literal lists.
  0-based indexed (first
                              · Lists are always flattened in Perl:
                                                                                      • If there are more variables than values: the extra variables are set to <u>undef</u>. Extra values are ignored.
  index is 0).
                                 • This means that (1, 2, (10, 20, (100, 200), 30, 40), 4) is exactly the same is (1, 2, 10, 20, 100, 200, 30, 40, 4). Use references to create nested data structures.
   Last index of array
  @name is $#name
                                                  Array containing ($days[0], $days[1], ... #days[$#days]) • A list is an ordered collection of scalars (of any type).
                               @days[3,4,5] Array slices containing ($days[3], $days[4], $days[5])
@days[3..5] Array slices containing ($days[3], $days[4], $days[5])

    An array is a variable that contains a list.

                                                                                                                      Reading beyond the end of array returns undef

    Negative indices used in read access from the end: -1 is last item.

                                  Use these negative indices to access from the end. Do not compute index with $#name -3, if the list size is 2, this will give invalid results.
                               • Use a slice to select multiple elements from a list, array, or hash.
                                                                                                                   my @extracted = (6, 2, 8, 4);
                                                                                                                                                                  my @digits = (0..9);

    array slices LPo

    Simple explanation

Don't use a slice when you know you need exactly one element.
An Ivalue slice imposes list context on the righthand side.

                                                                                                                   my @choices = @digits[@extracted]
my $mod_time = (state $filename)[9];
                                                                                                                                                                  my @one2five = @digits[1..5]:
                                                                                                                                                                 my @premiers = @digit[1, 2, 3, 5, 7];

    Assign to array slice to update several values. ⇒

                                                                                                                   @extracted[1, 3] = (7, 9):
                                 What are the advantages of anonymous array? @ StackOverflow Perlref @ Perldoc, Perl reference tutorial @ Perldoc

    Anonymous array := a type of array reference. Use it to build nested data structures.
    Array reference allows Perl to treat the array as a single item.

    Anonymous arrays

Hash/associative array
                                                                   Associative array (hash): keys-value pairs. Can be initialized as:
                                                                                                                                                           Initialize a hash slice with array context:
                                             %days
Hashes @ Perl Maven
Note: keys are always
                                                                                                                                                           @char_to_num{'A' .. 'Z'} = 1 .. 26;
my %rating = (ron => 20, al => 50, steve
                                                                     my %days = (Jan => 31, Feb => $leap? 29 : 28, ...)
my %days = ("Jan", 31, 'Feb', $leap? 29 : 28, ...
                 strings.
                                                                       Multiple values of a hash can be changed with the following construct:
                                                                                                                                                           # use fat comma to quote word left of it. 9
hash slice LPo
                                                                                                                                                           my @names = ('ron', 'al');
                                             @days{'J',F'}
                                                                  Hash slice returning a list containing ($days{'J'}, $days{'F'}).
                                                                                                                                                           @rating{ @names } = (25, 35); # update ron & al's ratings
key-value slices LPo →
                                         extract/write values:
                                                                  my scores = @rating{ @names }; @rating { @names } = (45, 55);
                                                                   & is needed to create reference to subroutine.

dereferencing
                                                                                                                                                         • &{ $the_function } (arg1, arg2);
• $the_function->(arg1, arg2);
Reference to subroutine
                              Store a ref to a subroutine:
                                                                   my $fct_ref = \&the_function;
                                                                                                                   Indirect calls:
                                                                                                                   with the simpler arrow notation:
                               Using an anonymous subroutine, always calling it indirectly:
                                                                                                                   my p = sub \{ my v1 = shift; my v2 = shift; return v1 ** v2; \};
                                                                                                                    say $op->(10, 4); # prints 10000
                                                                                                                   sub make_greeting {
  my $greet = shift;
  my $greet_fct = sub {
    my $name = shift;
}
Closures
Perl closure
                               A closure binds its environment and keeps it to use it when invoked.
                                 In the example at right, a greeter function is built and returned,
                                 rm the example at right, a greeter function is built and returned,
remembering how to greet. It is used like this:
    my $fr = make_greeting("Bonjour");
    my $it = make_greeting("Buongiorno");
    $fr->('Brigitte'); # prints: "Bonjour, Brigitte!\n"
    $it->('Madonna'); # prints: "Buongiorno, Madonna!\n"
                                                                                                                                print "$greet, $name!\n";
                                                                                                                          return $greet_fct; # return ref to internal function
                               A code block defining lexical variable(s) and subroutines consist of a
                                                                                                                    { my $count;
                               closure too! With the following example, the add_1() subroutine increments the $count and that's returned by get_count(). The
                                                                                                                       sub add_1 { count += 1; }
                                                                                                                      sub get_count { return count; }
                               $count variable cannot be accessed from anywhere else!
Scalar values
                                                                      literals examples: Note: leading 0 work only for literals, not for string-to-number conversions.
                                                                                                                                                                                       Useful related builtin functions

                                                                                              my \ $x = 0xff55;

    string

                               • double-quoted strings: perform backslash and variable interpolation of expression that begin with $ (a scalar) or @ (an array). Hashes cannot be interpolated.
                                 single-quote strings: only perform \' and \\ substitution (to ' and \ respectively), nothing else.
                                 Single quote and double quote strings can spread multiple lines: it embeds the newline character on each new line.
                                 \n is only expanded in double quoted strings. In single quote string it is treated as two characters; no substitution is done (as explained above).
```

File handle Variables	See also: Perl File Handles		The following variables a	are used in the Input/Output handlin	ng as well as program ar	guments.
Name of current file read from <>	\$ARGV		arguments of the script nd operator <>. →	@ARGV	Number of arguments minus one	\$#ARGV
Special file handle that iterates over command-line filenames in @ARGV	ARGV		dle that points to output file when doing ocessing	ARGVOUT		
Output field separator for the print operator	• IO::Handle->output_field • \$OUTPUT_FIELD_SEPA • \$OFS • \$,	_separator(EXF ARATOR	PR)	Current line number for the last file handled accessed	• HANDLE->input • \$INPUT_LINE_N • \$NR • \$.	line_number(EXPR) UMBER
Input record separator (newline by default)	• IO::Handle->input_record • \$INPUT_RECORD_SEP. • \$RS • \$/		PR)	Output record separator	• IO::Handle->output • \$OUTPUT_RECCC • \$ORS • \$\	at_record_separator(EXPR) DRD_SEPARATOR
Auto-flush control order of output @ Perl Maven Suffering from Buffering?	HANDLE->autoflush(EX SOUTPUT_AUTOFLUSF \$I		Perl activates file buffering by default. Assign 1 to \$ to activate auto-flush.	Last read file handle	\${^LAST_FH}	

Perl 5 Input/Output

Perl 5 Built-in Functions

Perl Functions Perl syntax	To get information about a Perl function from the command line use the perldoc -f command. • To get information about print use: perldoc -f print
! Cautionary notes	Some of the Perl functions exhibit various limitations and the vary over Perl versions. This section describes the ones I am aware and the proposed alternatives.
each keyword is broken	Do NOT use the built-in each. It is broken, as described by <u>Damian Conway</u> in his <u>Modern Perl Best Practice O'Reilly course</u> , section control structure. • each is not re-entrant:
 Use <u>Var::Pairs</u> instead. 	nested loops of each over the same hash does not work as expected and will create infinite loop since the nested loop each juts iterates from where the first loop each left it.
ilisteau.	 Exiting the loop leaves the state of the each internal pointer at the current location. If you use each on the same hash later it will resume from where it left, it will not start form the beginning.

Perl 5 Statements

	Perl 5 Statements ###								
Loop control	See perlsyn for more informati	on on Perl syntax	which includes declaration	ons, blocks, loops, labels, subrouting	nes, etc				
Use the last and redo inside a naked block of code to control looping.	Ioop control keywords: • last of exits the loop. • next of starts the next iteration of the loop. • redo of restarts the loop block without evaluating the condition again. The last, next, and rework in the following con • while (condition of the loop). • until (condition of the loop). • for (init; condition of the loop). • naked block: {			ion) { } ion) { } on; continue) { } }	Notes: • The while and foreach loops may have a continue block: executed before evaluating condition again, which corresponds to the 3rd part of a for loop statement. See this @ stackOverflow. • Blocks can be labelled of as targets to last, next, and redo				
Statement modifiers	if EXPR unless EXPR while EXPR until EXPR for LIST foreach LIST when EXPR	The for and foreach statements impose a list context; the complete list is processed. Therefore a loop like the following trying to stop on a line that has "_END_" on it will not work since it reads all of STDIN: foreach (<stdin>) { last if ?_END/; ; }</stdin>			The while statement imposes a scalar context; it takes one line at a time from <stdin> and the following code works properly: while (<stdin>) { last if /_END/; ; }</stdin></stdin>				
do block	The do block is *very useful* to set a value based on several conditions, just as the ?: conditional operator but with an explicit block that may use scoped variables. Takes advantage of a block value is the value of the last expression executed inside the block. Do *not* return from the block. The last, next and redo cannot be used inside do blocks.			if (\$perl_nirvana < 5 & elsif (some_other_cond elsif (\$emacs_nirvana	<pre>acs_nirvana) = check-nirvana-levels(); a</pre>				
Compound statements									
if, elsif, else									
unless									
?: conditional operator									

Perl subroutines	See Object Oriented Perl, section 2.1.4 : Subroutines							
Defining subroutine	Defined with the <u>sub</u> keyword followed by a b	lock.	<pre>sub greet { print "hello!\n"; }</pre>					
Calling subroutine	If the definition has not been seen before the oparentheses after the subroutine name are required.		But if the definition was above the call, the parentheses Subroutine sigil is &. It can optionally be used in a call;					
subroutine &	Why we teach the subroutine ampersand Why should I use the & to call a Perl subroutin	e? @ StackOverflow	Another point of view: <u>Subroutines and Ampersands</u> Note it must be used to <u>make a reference</u> to a subroutine	ne: \$greeter = \& greet;				
subroutine arguments passed by list always variable by nature	The arguments passed to a subroutine are avaspecial array. The caller code supplies a list of values. Remensed lists lists are flattened in Perl.		@sorted = alpha_order('Nice', 'Québec', 'Montréal'); @sorted = number_order @unsorted_numbers; @sorted = alpha_order('Trois-Rivières', @sorted, 'Gaspé', 'Rimouski');					
• named arguments Note: The @_ is an alias to the passed values; changing them inside the subroutine affects the caller's values.	Since hash declaration take a list of key/value implement a passing named arguments! It's also possible for the subroutine to set defa expected arguments by taking advantage of the lists, list are flattened and hash can be assigned values are used.	aults for some of the ne fact that hash are	<pre>Implementation: sub move { my (%directions) = @_; } Caller: move(up=>3, left=>4); move('down', 2); # it's by convention! To set a default: sub move { %default = (up=>0, down=0, left=>0, right=>0); my (%directions) = (%default, @_); }</pre>					
Subroutine Prototypes	An older Perl feature. Clashes with subroutine sign	gnatures as of Perl v5.20.	In Perl >= v5.20 put the :prototype attribute before sub	proutine prototype parenthesis.				
Subroutine signatures	Exactly zero arguments	()	Zero or 1 argument, no default, unnamed:	(\$=)				
 Perl >=5.36: Stable Perl >= 5.20: 	Zero or 1 argument, no default, named	(\$val=)	Zero or 1 argument, named, with default	(\$val=1)				
Experimental See: Use v5.20	exactly 1 named argument:	(\$val)	Exactly 2 arguments	(\$v1, \$v2)				
subroutine signatures	2, 3 or 4 arguments no defaults: (\$v1,	\$v2, \$=, \$=)	2,3 or 4 arguments, 1 default:	(\$v1, \$v2, \$v3='a', \$=)				
	Two or more, any number of arguments.	(\$v1, \$v2, @)	Two or more arguments, remainders into a named array:	(\$v1, \$v2, @rest)				
	Two or more arguments: an even number	(\$v1, \$v2, %)	Two or more arguments, remainders into a named hash:	(\$v1, \$v2, %rest)				
	Class method	(\$class,)	Object method	(\$self,)				
Returned value. Detecting calling context with wantarray	 The result of the last evaluated expression is implicitly returned. The return operator can be used but it's not required unless used to change execution flow (return immediately from the subroutine). The subroutine can return a scalar in scalar context or a list if called in list context. Inside the subroutine, use the wantarray function to determine the calling context of the subroutine call and why it should return: 							

Perl 5 Modules

The caller built-in returns information about the subroutine caller inside an array: (package, file_name, file_line). In scalar context it returns the package only.

Identify <u>caller</u>

Perl Modules								
Perl core modules	How to detect where a module is installed : perldoc -1 Module How to check if a module is part of Perl core : corelist Module (Perl >= v5.9.2)							
Access to Modules	Provide access to modules in your code with one of the following: do , require or use							
Modules @perItutorial Modules Using simple modules ♂	Looks for the module file by searching the EINC path. Performed at run time (and therefore can be done conditionally). If Perl finds the file, it places the code inside the calling program and executes it. Otherwise, Perl will skip the do statement silently. The "included" code does not have access to the lexical variables from the main program. Skip the @INC path lookup if given a file path starting with ./,/, or/							
	Loads the module file once, also searching the <u>@INC</u> path. Performed at run time (and therefore can be done conditionally). • If the require for the same file appears twice, Perl ignores it. Perl will issue an error message if it cannot find the file (as opposed to <u>do</u>). • Skip the <u>@INC</u> path lookup if given a file path starting with ./,/, or /							
The <i>normal</i> way to access Perl modules ➡	Similar to require except that Perl applies it before the program starts: it's done at compile time. Modify it dynamically in a BEGIN block. See IntPo . • Therefore the use statement cannot be invoked inside conditional statements such as if-else. Used often to include a module in a program. That imports the defaults as defined by the module's code. Select what to import with one of the two equivalent forms: (See IntPo): • use Module::Name ('function_a', 'function_b'); • use Module::Name (); # import nothing. All accesses to the module must be done with Module::Name::something							
Error handling for: Can't locate in @INC How to fix that See Also: IntPo See: show-perl-inc @ USRHOME	For the above statements to work Perl must be able to identify the location of the requested module(s). • Perl looks for a module code inside the directories identified by the energy-limits . • Perl looks for a module code inside the directories identified by the energy-limits . • Perl looks for a module code inside the directories identified by the energy-limits . • Perl looks for a module code inside the directory inside each energy-limits . • Perl looks for a module code inside the directory inside each energy-limits . • Add energy-limits inside your code, Perl looks for a sub-directory named 'The' containing a file named 'Module.pm' inside each energy-limits . • Add the required directory to the list of directories identified in the 't' separated list in the PERL5LIB environment variable. (use 't' as separators in Windows). • Add a use limits path/to/the/directory'; statement inside your Perl file to add the required directory when executing a specific piece of Perl code, at compile time. • Run Perl with the -I.(capital i) option to run the code with the extra directory added to energy-limits piece of Perl code, at compile time. • Run Perl with the -I.(capital i) option to run the code with the extra directory added to energy-limits piece of Perl code, at compile time. • To List the directories used by Perl from one of the following equivalent command lines: • perl -e 'print join("\n", @INC), "\n"; '							
Specially Named	• perl -le 'print for INC';' You can also get more information with perl -V 5 specially named blocks are run at the beginning or end of a running program: BEGIN, UNITCHECK, CHECK, INIT and END.							
Blocks	See: BEGIN block - running code during compilation. Note the security risk warnings. The BEGIN block is used to implement other Perl functionality.							
Declare <u>packages</u>	In Perl a package can span several files and one file may contain the code of several packages. The package starts with the package keyword. The specialPACKAGE literal contains the name of the current package.							

Topic: Data Introspection

Data Introspection								
Using Perl Debugger	Debug a pro	ogram:	perl -d program	_name	name program_args			
Debugger Tutorial	Debug inter	ractive session:	perl -d -e 0					
Debugger commands	q	Quit debugger		s	single step			
	h	help. List all availa	ıble commands.	x	evaluate expression			
Modules for Data introspection				• Pas	s similar to the x command of the debugger. ss reference to the variables, otherwise it extends them to and show each entry as its own variable.	<pre>• print Dumper(\@array); • print Dumper \\@array;</pre>		
				comp	des a dump function that has nicer output, but is not <u>eval</u> patible. mp() prints on the stdout. No need to use print.	use Data::Dump qw(dump); dump(\@array); dump(\%hash);		
 Data::Printer compatible. It provides the p subroutine that does not require to the variable as it inspects it first. p() prints on the stdout. No need to use print. 					use Data::Printer; p(@array); p(%hash);			
Data Marshalling Data Serialization		everal modules, eith		re or o	utside, that provides mechanism to marshall/serialize and	unmarshall/de-serialize data.		

Topic: Directory Operations

			· ·
Directory Operations	In Books: LPo		
Opening Files	All file open operations are relative to the <u>current working</u> relative file names)	ng directory (for	open my \$filehandle, '<:utf8', 'a_relative/path.txt'
Creating temporary files	File::Temp (Perl >= v5.6.1). <u>Using File::Temp</u> • Also see <u>IO::File</u>		
Built-in Functions	Related Functions/Packages / Descriptions		Notes
Getting file names by: Globbing: with glob	File::Glob (Perl >= v5.6.0) - provides more control.	Example:	<pre>my @all_files = glob '*'; my @perl_files = glob '*.pm *.pl'; # 2 globs, space-separated</pre>
with the glob operator <>	The <> operator is identifying: a filehandle, when: the item inside <> is a Perl identifier or an indirect file handle read scalar, a glob expression otherwise.	Glob examples:	<pre>my @all_files = <'*'>; my @all_files = <*>; # 1 glob: no space, no need for string my @perl_files = <'*.pm *.pl'>; # 2 globs, space-separated</pre>
operator V			<pre>my \$etc_dir = '/etc'; my @etc_dir_files = <\$etc_dir/* \$etc_dir/.*>;</pre>
			my @files = <larry *="">; # a glob</larry>
	See: <u>readline</u>	Filehandle	<pre>my @his_lines = <larry>; # a filehandle read</larry></pre>
		examples:	<pre>my \$name = 'LARRY'; my @his_lines = <\$name>; # indirect filehandle read of LARRY handle my @same_lines = readline LARRY; # another way to write above my @same_lines = readline \$name;</pre>
 with a directory handle LPo 	opendir: open a directory: get a directory handle readdir: read the directory handle. But see this. closedir: close the directory handle. DirHandle (Perl <= 5.5) File::Spec::Functions (Perl >= v5.5.4) Path::Class	Example: iterate explicitly over a list of file names extracted from the directory using these 3 functions.	<pre>my \$dir = '/usr/bin'; opendir my \$dh, \$dir or die "Failed opening \$dir: \$!"; foreach \$file (readdir \$dh) { print "File \$file is inside \$dir\n"; # 1 no path in name! } closedir \$dh;</pre>
Creating directory	• mkdir	Example:	<pre>mkdir \$dir_name, oct(\$permissions); # octal for permissions mkdir \$dir_name, 0700; # do not use "0700", it's 700 decimal!</pre>
Removing directory	rmdir Removes an empty directory. File::Path remove tree , rmtree remove dir & files (Files remove dir & files (Files remove dir & files remove dir & files (Files remove dir & files remove dir &	Perl >= v5.0.1)	
Removing files	• unlink a list or \$_		<pre>unlink 'file1.txt', 'file2.txt'; unlink qw(file1.txt file2.txt); unlink glob 'file?.txt'</pre>
Renaming files	rename an old file name to a new one. The fat comma operator is sometimes used to highlight what is the old and the new name.	As in here:	<pre>rename 'old_name' , 'new_name'; rename old_name => 'new_name'; # use fat comma to quote word left of it.</pre>
Changing permissions	chmod changes file permissions		
Changing ownership	chown changes file ownership		
Creating Hard link	link to create a hard link		
Creating symbolic link	symlink to create a symbolic link		
chdir Change current working directory	File::chdir File::HomeDir	• chdir without \$ENV{LOGDIR	argument attempt to change to user home directory using the \$ENV{HOME} and element values if they are set. The File::HomeDir module helps in setting them. dir is global for the entire program. Use File::chdir facilities for localized operations.
Modules	Functions Legend: Exported by default, exported on request, W.	in32 specific	Extra Information
Cwd	getcwd, cwd, fastcwd, fastgetcwd, getdcwd abs_path, realpath, fast_abs_path		<pre>use Cwd; my \$curdir = getcwd; print "cwd is \$curdir\n";</pre>
File::Basename	fileparse, basename, dirname,		
File::Spec File::Spec::Functions	functional interface to methods: canonpath, catdir, splitpath, splitdir, catpath, abs2rel, rel2abs. All can be		otdir, updir, no upwards, file name is absolute, path. devnul, tmpdir, case tolerant, ng the :ALL tag.
File::Find : Traverse a directory tree. See: File::Find::Closures	find, finddepth, %options. In wanted: File::Find::dir, Note that \$_gets the base name of the file (no path). It perform filetest operations in the example here (as expl -s, and implicit argument to -d and -f). This traverses the	is used to icit argument to	use File::Find; find(sub {printf("- %-10s : %4d, %s\n", \$_, -s \$_, File::Find::name) if (-d or -f) and (\$_ ne "."); }, '.'); # in the above it lists the names of files inside all directories not showing the directory name

Topic: List Operations

List Operators								
Sorting lists	sort	Sort a list	<pre>my @sorted = sort @unsorted_list;</pre>	in place: my @data = sort @data;				
	reverse	Sort a list in reverse order	my @rsorted = <u>reverse</u> @unsorted_list;	in place: my @data = <u>reverse</u> @data;				
Filtering list with grep	my @adult_	ages = grep \$_ > 18, @ages;	my @lucky_ages = grep /7\$/, @ages; # all that end with 7	my @read_ages = grep { \$_ >= 7 && \$_ <= 77 } @ages;				
Counting matches	my \$count	= grep \$_ > 18, @ages;						
		An expression, subroutine or block with trailing boolean can be used as the grep criteria. Each item in the list is identified inside grep by \$						
Transform a list with map								

Topic: Process control

			Topic: Process control 🚜		
Process Control	In Books: LPo Important security information: peridoc perisec				
Environment Variables	Inside the <u>%ENV</u> hash. Perl <u>%Config</u> ha • To use it: us		ash: Perl configuration information. For example, whether it support threads, what are path separators, etc se Config;		
Built-in Functions	Example		Description/ Notes		
system (2 functions)using the shellsecurity risk?	<pre>system 'ls -1 \$HOME';</pre>		Run child process asynchronously using parent's stdin, stdout and stderr, using the OS native command shell.		
	<pre>system "cd \$project; make &";</pre>		Use the Unix shell to execute a long running build asynchronously. However: avoid using the shell like this. Using the shell to build commands from unvalidated user input data may lead to security issues.		
avoiding the shell	system 'tar', 'cvf', \$tarfile, @directories;		No shell invoked when more than 1 argument is passed to system. No shell interpretation, piping, re-direction done.		
 other syntax 	system('tar', @arguments);		O means success: unless (system 'tar', arguments) { print "tar command success\n"; }		
	system({ \$prog }, \$arg0, @args);				
	Note that if the string contain no shell metacharacters it is executed directly (not through a shell).				
 system return value: A value of 0 usually means all was OK. 	2 bytes: MSByte: child pro	gram exit code.	my \$retval = system();		
	LSByte: system-specific information bits: • 0x80 : set on core dump. • 0x7f : signal number		my \$childp_exitcode = \$retval >> 8;		
exec	Unlike system, exec does not return to the parent Perl process. Use: exec 'the_program' or die "Could not run: \$!"; #or warn or exit				
backquotes``	Use backquotes to capture the The trailing newline is not file.		gram. That's the main point of using it. e filter by <u>chomp</u> .	<pre>chomp(my \$current_date = `date`);</pre>	
	 invoke the shell if there are a The following example bu Note that `` is also written 	any shell meta-cha uilds a dictionary (n as qx/ /	e the single double quote string argument of system: it will aracters and supports interpolation. hash) of topics with the text extracted from peridoc. 1 string. In list context it returns a list of strings (1 per line).	<pre>my @topics = qw(die warn exit); my %info; foreach (@topics) { \$info{\$_}} = `perldoc -t -f \$_`; }</pre>	
Modules					
Capture streams	Capture::Tiny Can be used to capture the stdout and stderr streams for various ways if executing other programs				
Inter-process support	Can also be used to capture streams and provide more inter-process support. • It provides systemx which never uses the shell, along with other useful functions.				
Processes as filehandles	In Books: LPo				
Perl - program	Launching a process that pipes into the Perl process	open DATE, 'dat	e or die "Cannot pipe from date: \$!";	Use a bare word to define the DATE file handle.	
			fh, '- ', 'date' or die "Cannot pipe from date: \$!";	This one and the others define a local file handle variable. The file handle variable can later be used to read, as the above one, but is not global.	
		open my \$ps_fh	, '- ', 'ps', 'aux' or die "Cannot pipe from ps: \$!";		
		open my \$find_fh, '- ', 'find', qw(name '*.p[lm]' -print) or die "Cannot pipe from find: \$!";			
Perl ➡ program	Launching a process that the Perl process pipes into.			die "Cannot pipe to the dispatcher: \$!";	
Forking	In Books: LPo. See also: Linux fork(2) system call, QA: Why do we need fort to create new processes? Why fork woks the way it does?				
fork with exec and waitpid See also: Other IPC functions Perl IPC	 fork the process into parent and child. in the child process start the program with exec In the parent process wait for the program termination with waitpid defined(my \$process_id = fork) (\$process_id) { # Inside the child process (created by fork) # Exec 'long_running_process' or die "Failed starting long_running_process: \$!"; # Inside the parent process, wait for completion of long_running_process. * Inside the parent process, wait for completion of long_running_process. 				
<u>Signals</u>	In Books: LPo				
kill	Sends a signal to a list of processes. kill 'INT', \$pid or die "Can't signal \$pid with SIG				
	 The signal may be identified by number or name (string), which is more portable. The <u>\$Config{sign_name}</u> provides the supported signal names. 				
	• Note that the <i>fat comma</i> operator (=>) can be used to automatically quote signal name: kill INT => \$pid or die "Can't signal \$pid with SIGINT: \$!";				
	If the signal is 0 or "ZERO" signal to the process: ie: if the signal to	unless (kill 0, \$process_id) { warn "Process \$process_id is no longer running!"; }			
	If the signal is a negative nu identified by the process sc.		nat starts with '-' the signal is sent to the process group	• <u>kill</u> '-KILL', \$process_group • <u>kill</u> -9, \$process_group	
Signal handlers	• Set the signal handler by setting <u>%SIG</u> for the signal name (with no 'SIG' prefix) to a string holding the name of the subroutine.				
	I a				

PerlTidy formatting control *******

• $\underline{\text{Log::log4per!}}$ is an implementation of the popular Apache $\underline{\text{Log4j}}$ for Perl.

	Territay formatting control was		
perItidy option	Option	Impact	
indentation style	bl,opening-brace-on-new-linebrace-left	 Without this option (the default) the code indentation style selected is <u>K&R style</u>. With this option, the indentation style is <u>Allman/BSD style</u>. 	

Perl supports the warn buil-in to generate warnings on stderr.
 The <u>Carp::carp</u> from the <u>Carp</u> package, provides more information.

Error Logging and Reporting
