Perl scripts

Writing Perl scripts	Impose strictures in Perl files to prevent errors by adding one of the following use lines. Also see the strictures package.						
Use the following at the beginning of Perl script files. perldiag @ perldoc	<pre>#!/usr/bin/env perl use strict; use warnings; # for testing only: use diagnostics;</pre>	#! /usr/bin/perl -w use v5.12; # loads strict use v5.35; # &loads warnings use diagnostics produces more info but increases startup time. Alternative: perl -Mdiagnostics . Emacs p	Executable Perl script should have a valid shebang line identifying the appropriate location of the Perl interpreter. It may have to be modified at installation time (OpenGroup/SUS). It's best to: use warnings; perl -w generates warning for all Perl code in the program including modules used by the program. Also use the _c option to check syntax. But most Perl code should also activate the strict Perl rules and warnings to detect warnings. See: Barewords in Perl eel-perl-critic command can report diagnostic.				
use version/features	<u>use</u> v5.36;	This can be used to enable both the strict and warning pramas as well as several <u>named features</u> . • See the <u>table listing the feature bundles per Perl versions</u> .

Perl 5 Operators
Perl 5 Operators
                             Perl operators, listed below with their precedence and associativity.
                                                                                                                                             C Operators missing from Perl: unary &, unary * and (type)
                   Note:
                             • Quote and Quote-like operators: in Perl quotes are operators and they provide various kind of interpolating and pattern matching capabilities
Associativity: one of:
                             left
                                          terms and list operators (leftward)
                                                                                                                                        Note: print, sort, reverse, chmod, are list operators
  right
                             1eft
                                          Arrow Operator:
  left
                             NA
                                                                                    ++ --
                                          Auto-increment and Auto-decrement:
• NA : not associative:
                             right
                                          Exponentiation:
  cannot use more than one of these operators
                             right
                                          Symbolic Unary Operators:
                                                                                     1 ~
                                                                                            -. \ and unary + and -
                                                                                                                                        Note: The operator \ creates a reference. See example.
                             left
                                          Binding operators:
   in sequence.
                             left
                                                                                            용
                                          Multiplicative Operators:
                                                                                     * /

    CH: chained

                             left.
                                          Additive Operators:
                             left
                                         Shift Operators:
                                                                                     <<
                                                                                            >>
                             NA
                                          named unary operators
To get this information.
                             NA
                                          Class instance Operator:
                                                                                    isa

                                                                                In scalar context localtime returns human readable time.
operators that achieve a
                                                                                                                                                     $ perl -le 'print ~~localtime'
                                                                                but in list context it returns a 9-tuple with date elements.
                                                                                                                                                       on Nov 30 09:06:13 2009
specific effect.

    Negation of a true value by "!" or "not"

Truth and falsehood
                             False in a boolean context:
                                                                                                          These scalar values are false:
                                                                                                                                                     All other scalar values are true, such as:
                                                                returns a special false value.

When evaluated as a string it is
                                                                                                             undef - the undefined value
                                                                                                                                                       1 and any non-0 number
                               • the number \mathbf{0},
 1 The strings '0' and ''
                                 the strings '0' and ''.

    0 the number 0, even if you write it

                                                                                                                                                         ' the string with a space in it
mean false. The output
                                                                treated as ", but as a number, it is treated as 0.
                                                                                                                                                     • '00' two or more 0 characters in a string
                                                                                                             as 000 or 0.0
                                  the empty list ().
of glob() may return a file
                                                                                                                                                     "0\n" a 0 followed by a newline'true'. 'false' . Even 'false' evaluates to true.
                                                                                                              the empty string.
                                   "undef
named '0'!
                                                                                                          • '0', a single 0 in the string.
 1 The bareword false
                              All other values are true.
                                                                                                                                               use constant { true => 1, false => 0 };
 has a truth value of true!
                             🤞 One way to define valid true and false constant symbols that can be used in assignments (but see 🗢):
                                                                                                                                               if (-e $fname && -f _ && -r _
File test operators
                             File tests can be stacked (-r -w -e $fname) or combined as in the following example or:
                                                                                                                                                r (-e $fname && -f _ && -r _ ) {
  print("$fname exists, is readable\n"); }
See filetest -X
                               Notice the underscore in the example: it's the virtual filehandle _ accessing the last stat or lstat result :
                                          is readable by effective uid/gid
                                                                                                                                                     is a block special file.
The operators check if
                                                                                       exists.
                                                                                                                                               -b
                                          is writable by effective uid/gid is executable by effective uid/gid
the file..
                                                                                       is empty.
                                                                                                                                                     is a character special file.

                                                                                                                                                      Functions/methods are lowercase_with_underscores
                                 Constants:
                                                     $UPPER_CASE
                              global by default
                                                                A variable defined without any of the following prefixed keyword is global by default.
Scope of variables
                                           local, lexical scope, non persistent
                              mv
                                                                                          Examples:
                                                                                                        \underline{\mathbf{m}}\mathbf{y} @values = (42, 36, 99); \underline{\mathbf{m}}\mathbf{y} ($v1, $v2) = (42, 36);
Scope of variables in Perl
                              state
                                           Local, lexical scope, persistent
                                                                                          Perl >= v5.10 Restriction: in Perl < v5.28: array and hashes state cannot be initialized in list context.
@Perl Maven
                                           Creates a lexical scoped alias to a package variable
                                           Localizes an existing package variable to the current scope. It's not a declaration. The variable previous value is restored when leaving the scope.
                              local

The <u>local</u> keyword was used to achieve localized variables before my variables existed, but it should no longer be used that way.
It should be used to localize modifications to a global variable or hash value.

                                                                                                               $#days
Perl types
                             $foo
                                                   Simple scalar value
                                                                                                                                    Last index of array @days.
Scalar
                              $days[28]
                                                   29th element of array @days
                                                                                                               $days->[28]
                                                                                                                                    29th element of array pointed to by reference $days.
                                                                                                                                    Multi-dimensional array
                              $days{'Feb'}
                                                    Value associated with the Feb key of hash %days
                                                                                                               $days[0][2]
                                                                                                              $d{99}{'Feb'}
$d{99, 'Feb'}
Archaic use of single
                              ${days}
                                                    Same as $days, use before alphanumumerics.
                                                                                                                                    Multi-dimensional hash
quote:
                                                                                                                                    Multi-dimensional hash emulation
                                                   The $days variable inside the Dog package.
            $Dog'days
                              $Dog::days
list and Array
                              @davs
                                                Array containing ($days[0], $days[1], ... #days[$#days])

    A list is an ordered collection of scalars (of any type).

                              @days[3,4,5] Array slices containing ($days[3], $days[4], $days[5])
                                                                                                                 An array is a variable that contains a list.
                              @days[3..5] Array slices containing ($days[3], $days[4], $days[5])
  index is 0).
                                                                                                                 Reading beyond the end of array returns undef
   Last index of array
                              • Negative indices used in read access from the end:
  @name is $#name
                                Use these negative indices to access from the end. Do not compute index with $#name -3, if the list size is 2, this will give invalid results.

    array slices LPo

                                Use a slice to select multiple elements from a list, array, or hash.
                                                                                                              my @extracted = (6, 2, 8, 4):
                                                                                                                                                           my @digits = (0..9)

    Don't use a slice when you know you need exactly one element.
    An Ivalue slice imposes list context on the righthand side.

                                                                                                              my @choices = @digits[@extracted]
my $mod_time = (state $filename)[9];
                                                                                                                                                           my @one2five = @digits[1..5];
my @premiers = @digit[1, 2, 3, 5, 7];
    Simple explanation

    Assign to array slice to update several values. ⇒

                                                                                                                  extracted[1, 3] = (7, 9);
                                What are the advantages of anonymous array? @ StackOverflow
                                                                                                              • Anonymous array := a type of array reference. Use it to build nested data structures.

    Anonymous arrays

                                                                                                               · Array reference allows Perl to treat the array as a single item.

print $$array_ref[1]; # b, simpler
print $array_ref->[1]; # b, arrow notation
                                                                                                                                                           print ${$hash_ref}{c}; # 3
print $$hash_ref{c}; # 3, simpler
                                                                                                              print $hash{c}: #3
Reference purpose

    drop brace around bareword ref.
    arrow notation is shorter/cleaner

IntPor

• brace around refs:
                              You can create complex data
                                                                                                                                                           print $hash_ref->{c}; # 3 with arrow notation
circumfix dereferencing:
                              my $data = [0, 1, 2, [40, 50, 60, [100, 200], 70], 8];
                                                                                                                                                                 my $hash_ref
                                                                                                                 Creale a lexical reference:
                             my detad = [0; , 2, ] n, 0, 00; [10, 200], n, n, n
print @{@{${$data}[3]}[3]}[0], "\n";
print $data->[3]->[3]->[0], "\n";
print $data->[3][3][0], "\n";

    Store a ref to an array or hash into an array: push @array \%hash;
    Pass array or hash to subroutine: fct(\@a, \%h); Return from sub: return (\@a, \%h);

· simplify with ->
                                                                            '\n"; #100
• simplify more
                                                                                   # 100

    Arrows between subscript are optional

                             (Perl >= v5.20.0) Instead of using a sigil prefix, it uses a postfix sigil and star. sref:ref to scalar, aref:ref to array, href:ref to hash, cref:ref to code, gref:ref to glob
postfix dereferencing
See: cool new Perl
                              $sref->$*; # same as
$aref->e*; # same as
                                                                                   $aref->$#*; # same as $#{ $aref } #last array idx
$href->%*; # same as %{ $href }
$gref->**; # same as %{ $gref }
                                                            ${ $sref }
feature: postfix
                                               # same as @{ $aref }
Reference to subroutine
                             Store a ref to a subroutine:
                                                                my fct ref = \ \ the function;
                                                                                                              Indirect calls:
                                                                                                                                                     • &{ $the function } (arg1, arg2);
                                                                                                                                                    • $the_function->(arg1, arg2);
                                                                                                               with the simpler arrow notation:
                                                                                                              my $op = sub { my $v1 = shift; my $v2 = shift; return $v1 ** $v2; };
                              Using an anonymous subroutine, always calling it indirectly:
                                                                                                               say $op->(10, 4); # prints 10000
                              A closure binds its environment and keeps it to use it when invoked.
                                                                                                               sub make greeting
Closures
                                                                                                                    my $greet = shift;
my $greet_fct = sub {
    my $name = shift;

    Perl closure

                              · In the example at right, a greeter function is built and returned,
                                remembering how to greet. It is used like this:
                                 my $fr = make_greeting("Bonjour");
my $it = make_greeting("Buongiorno");
$fr->('Brigitte'); # prints: "Bonjour, Brigitte!\n"
$it->('Madonna'); # prints: "Buongiorno, Madonna!\n"
                                                                                                                          print "$greet, $name!\n";
                                                                                                                      return $greet_fct; # return ref to internal function
                              A code block defining lexical variable(s) and subroutines consist of a
                                                                                                               { my $count;
  sub add_1 { count += 1; }
                              closure too! With the following example, the add_1() subroutine
                              increments the $count and that's returned by get count(). The
                                                                                                                 sub get_count { return count; }
                              $count variable cannot be accessed from anywhere else
Scalar values
                                                                   literals examples: Note: leading 0 work only for literals, not for string-to-number conversions.
                                                                                                                                                                               Useful related builtin functions

```

my x = 0xff55:

hexadecimal

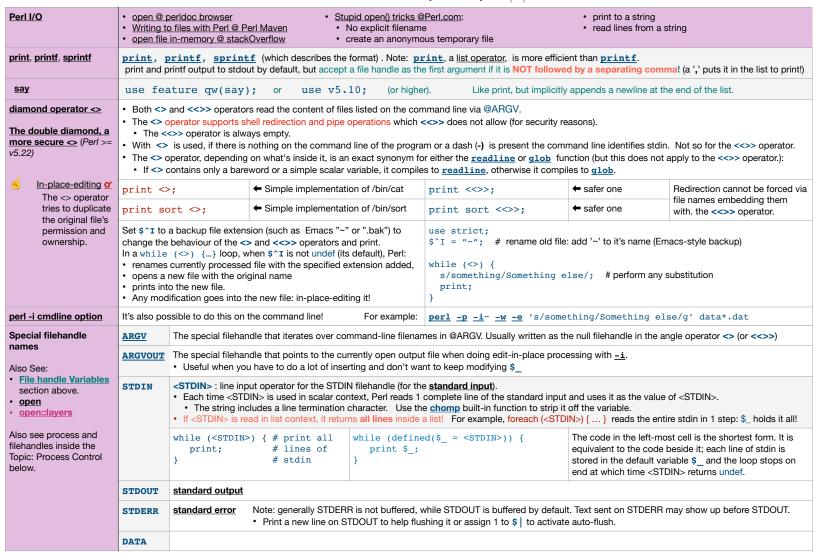

· string	 double-quoted strings: perform backslash and variable interpolation of expression that begin with \$ (a scalar) or @ (an array). Hashes cannot be interpolated. single-quote strings: only perform \' and \\ substitution (to ' and \ respectively), nothing else. Single quote and double quote strings can spread multiple lines: it embeds the newline character on each new line. \n is only expanded in double quoted strings. In single quote string it is treated as two characters; no substitution is done (as explained above).

• bareword					entifier. It's not quoted. By default subs"; or use v5.12; is specified		behave like strings.
Here documents Here docs @ Perl maven Perl here doc @Wikipedia	Perl here-documents are a form of line oriented quoting. There are several forms of here documents, where the identifier (like EOF used below, but can be any word) must be placed at the beginning of the terminating line: • Default: • CEOF; • Double quotes: • Single quotes: • Single quotes: • Deachticks: • CEOF; • Deachticks: • CEOF; • Dackticks: • Dacktic						
Perl Regexp	Regexp T	utorial, Learn PC	RE in X minutes, P	CRE cheatsheet,	<u>Debuggex</u> regexp tester, ı	regex101, RegEx Pal	
• index/substr	\$pos = <u>inc</u>	dex(\$page, \$line);	\$last_slash = <u>rin</u>	<pre>ndex("/usr/bin/ls", "/");</pre>	\$part = substr(\$text, \$pos, \$lendary	n) A value of -1 in pos ide	entifies last character.
Replacement manipulate strings with <u>substr</u> <u>LPor</u>	substr(\$p	= "I like awk and erl ref, <u>index(\$pref, "ar</u> ref, 0, 0) = "Sally ar	wk"), length ("awk"))		substr(\$pref, -15) =~ s/Perl/Per	rl5/g; # replace text inside	a restricted portion of the string.

Perl 5 Special Literal and Variables

			-					
Special Literals								
	FILE : current file name LINE : current line number	•PACKAGE : curre •SUB : refer	ent package name ence to current subroutine		indicate logical end of script but supports reading text			
Perl Special Variables • Perl Variables	To get information about a Perl special variable from the command line use the perldoc -v command. To get information about \$< use: perldoc -v '\$<'							
Deprecated and removed variables:	\$# \$* \$[\${^ENCODING} \${^WIN32_SLOPPY_STAT}							
General variables	Note that the \$, @ and % prefixes are the sigil that	at identify the scalar, array	and hash access context. The na	me of the variable is plac	ed after that character.			
default input and pattern searching space	• \$ARG • \$_		subroutine parameters	• @ARG • @_				
list separator	• \$LIST_SEPARATOR • \$"		Subscript separator for multidimensional array emulation	• \$SUBSCRIPT_SEL • \$SUBSEP • \$;	PARATOR			
Name of executed program	• \$PROGRAM_NAME • \$0		Name used to execute the current copy of Perl	• \$EXECUTABLE_I • \$^X	NAME			
Perl process ID	• \$PROCESS_ID • \$PID • \$\$	Process real GID	• \$REAL_GROUP_ID • \$GID • \$(Process effective GID	• \$EFFECTIVE_GROUP_ID • \$EGID • \$)			
Process real UID	• \$REAL_USER_ID • \$UIG • \$<		Process effective UID	• \$EFFECTIVE_US: • \$EUID • \$>	ER_ID\$			
Special variables in sort								
Current environment	%ENV		cessed as an associative array (a heess shell environment variables thro		ays.			
Perl interpreter revision, version and subversion	• \$OLD_PERL_VERSION • \$]		Perl interpreter revision, version and subversion	• \$PERL_VERSION • \$^V				
Maximum file descriptor	• \$SYSTEM_FD_MAX • \$^F		Fields of each line when auto- split mode is on.	@F				
Include Directories	@INC	Included filenames	%INC	Hook localization (?)	\$INC			
inplace-edit extension value	• \$INPLACE_EDIT • \$^I	Package's class parent classes	@ISA	Emergency memory pool	\$^M			
Maximum block nesting	\${^MAX_NESTED_EVAL_BEGIN_BLOC	KS}		Time when program began running	• \$BASETIME • \$^T			
Name of OS where this Perl was built	• \$OSNAME • \$^O	Signal handlers	%SIG	Coderefs for various perl keywords	%{^HOOK}			
Regexp Variables								
captured sub-patterns	\$ <digit>(\$1,\$2,)</digit>		Capture buffer content	@{^CAPTURE}				
String matched	• \$MATCH • \$&		String matched (compiled regexp)	\${^MATCH}				
String preceding match	• \$PREMATCH • \$`		String preceding match (compiled regexp)	\${^PREMATCH}				

String following match	• \$POSTMATCH • \$'			String following match (compiled regexp)	{^POSTMATCH}		
Last capture group	• \$LAST_PAREN_MATCI • \$+	H		Most recently closed capture group	• \$LAST_SUBMAT • \$^N	TCH_RESULT	
Match capture key values	• %{^CAPTURE} • %LAST_PAREN_MATC • %+	Н		Maximum regexp nested group	\${^RE_COMPILE_RECURSION_LIMIT}		
Match start offsets	• @LAST_MATCH_STAR • @-	Т	Match ends offsets	• @LAST_MATCH_END • @+	Named captured groups	• %{^CAPTURE_ALL} • %-	
Last successful pattern	\${^LAST_SUCESSFUL_PA	ATTERN}	Result of last successfu	Il regexp assertion	\$^R • \$LAST_RE	GEXP_CODE_RESULT	
regexp debug flag	\${^RE_DEBUG_FLAG}			regexp internal optimization/memory	ory \${^RE_TRIE_	MAXBUF}	
Format Variables	The format mechanism is us	se to generate p	rinted layouts. It's an o	old Perl feature but still useful in v	various places.		
Current value of the write() accumulator for format() lines.	• \$ACCUMULATOR • \$^A						
Form feed format. defaults to \f	• IO::Handle->format_form • \$FORMAT_FORMFEED • \$^L			Set of characters after which a string may be broken to fill continuation fields		at_line_break_characters EXPR _BREAK_CHARACTERS	
Number of lines left on the page on currently selected output channel	• HANDLE->format_lines • \$FORMAT_LINES_LEF • \$-			Current page length of current output channel	• HANDLE->forma • \$FORMAT_LINE • \$=	nt_lines_per_page(EXPR) S_PER_PAGE	
Name of current top- page format of output channel	HANDLE->format_top_r\$FORMAT_TOP_NAME\$^			Report format name of output channel	HANDLE->forma\$FORMAT_NAM\$~	_ ` /	
• Error Variables				types of error conditions that may a ating system, or an external prograr		of a Perl program.	
Perl error from the last eval operator	• \$EVAL_ERROR • \$@			Current state of interpreter	• \$EXCEPTIONS_1 • \$^S	BEING_CAUGHT	
Current value of C errno integer variable	\$OS_ERROR \$1 returns the system variable errno when used in a numeric context, but returns the string from perror() when used in string context.			Hash of error names to 0 or 1, set to 1 if current error is this error.	• %OS_ERROR • %ERRNO • %!		
OS detected error	• \$EXTENDED_OS_ERRO	OR	• \$^E				
Status returned by last pipe close, backtick command, wait, waited, or system() call.	• \$CHILD_ERROR • \$?			native status returned by last pipe close , backtick command, wait() or waitpid() or system() call	\${^CHILD_ERROR_NATIVE}		
Current value of warning switch	• \$WARNING • \$^W			Current set of warning checks enabled by the use warnings pragma	\${^WARNING_BITS}		
Variables related to the interpreter state	These variables provide inform	ation about the c	urrent interpreter state.				
Flag associated with the -c switch	• \$COMPILING • \$^C			The current value of the debugging flags	• \$DEBUGGING • \$^D		
Current phase of the perl interpreter	\${^GLOBAL_PHASE}			Debugging support. Internal variable.	• \$PERLDB • \$^P		
Compile-time hints for the perl interpreter. Internal use only	\$^H			Values of compiled statements	%^H		
Taint mode	\${^TAINT}			Safe locale operations availability	\${^SAFE_LOCALE	S}	
Input/Output Layers. Internal use by PerlIO only.	\${^OPEN}			Unicode Settings of Perl	\${^UNICODE}		
Internal UTF-8 offset caching code state	\${^UTF8CACHE}			State of UTF-8 locale detected by perl at startup.	\${^UTF8LOCALE}		
File handle Variables	See also: Perl File Handles		The following variables	are used in the Input/Output handlir	ng as well as program ar	guments.	
Name of current file read from <>	\$ARGV		arguments of the script nd operator <>. ➡	@ARGV	Number of arguments minus one	\$#ARGV	
Special file handle that iterates over command-line filenames in @ARGV	ARGV		dle that points to butput file when doing occessing	ARGVOUT			
Output field separator for the print operator				Current line number for the last file handled accessed	 HANDLE->input_line_number(EXPR) \$INPUT_LINE_NUMBER \$NR \$. 		
Input record separator (newline by default)	• IO::Handle->input_record • \$INPUT_RECORD_SEP. • \$RS • \$/		PR)	Output record separator		ut_record_separator(EXPR) DRD_SEPARATOR	
Auto-flush control order of output @ Perl Maven Suffering from Buffering?	HANDLE->autoflush(EX SOUTPUT_AUTOFLUSI \$1		Perl activates file buffering by default. Assign 1 to \$ to activate auto-flush.	Last read file handle	\${^LAST_FH}		

Perl 5 Input/Output

Perl 5 Built-in Functions

	Peri 5 Built-in Functions 777
Perl Functions Perl syntax	 To get information about a Perl function from the command line use the perldoc -f command. To get information about print use: perldoc -f print
Cautionary notes	Some of the Perl functions exhibit various limitations and the vary over Perl versions. This section describes the ones I am aware and the proposed alternatives.
 <u>each</u> keyword is broken 	Do NOT use the built-in each. It is broken, as described by <u>Damian Conway</u> in his <u>Modern Perl Best Practice O'Reilly course</u> , section control structure. • each is not re-entrant:
Use <u>Var::Pairs</u> instead.	 nested loops of each over the same hash does not work as expected and will create infinite loop since the nested loop each juts iterates from where the first loop each left it. Exiting the loop leaves the state of the each internal pointer at the current location. If you use each on the same hash later it will resume from where it left, it will not start form the beginning.

Perl 5 Statements

				1 1	
Loop control	See <u>perlsyn</u> for more informati	ion on Perl syntax wh	hich includes declaration	ons, blocks, loops, labels, subrouting	nes, etc
Use the <u>last</u> and <u>redo</u> inside a naked block of code to control looping.	loop control keywords: last of: exits the loop. next of: starts the next iteration of the loop. work in the follow while (until (on) { } on) { } n; continue) { } . }	Notes: • The while and foreach loops may have a continue block: executed before evaluating condition again, which corresponds to the 3rd part of a for loop statement. See this @ stackOverflow. • Blocks can be labelled of as targets to last, next, and redo
Statement modifiers	if EXPR unless EXPR while EXPR until EXPR for LIST foreach LIST when EXPR	The for and foreach statements impose a list context; the complete list is processed. Therefore a loop like the following trying to stop on a line that has "_END_" on it will not work since it reads all of STDIN: foreach (<stdin>) { last if ?_END/; ; }</stdin>			The while statement imposes a scalar context; it takes one line at a time from <stdin> and the following code works properly: while (<stdin>) { last if /_END/; ; }</stdin></stdin>
do block	The do block is *very useful* to set a value based on several conditions, just as the ?: conditional operator but with an explicit block that may use scoped variables. Takes advantage of a block value is the value of the last expression executed inside the block. Do *not* return from the block. The last, next and redo cannot be used inside do blocks.			<pre>if (\$perl_nirvana < 5 & elsif (some_other_cond elsif (\$emacs_nirvana</pre>	<pre>ccs_nirvana) = check-nirvana-levels(); \$\emacs_nirvana < 8) { 'study-Perl' } l()) { 'time-to-cook' } < 7) { 'look-into-eieio' } go-skiing' : 'go-canoeing' }</pre>
Compound statements					
if, elsif, else					
unless					
?: conditional operator					

Perl 5 Subroutines

Perl subroutines								
subroutine &	Why we teach the subroutine ampersand Why should I use the & to call a Perl subrouting	e? @ StackOverflow	Another point of view: Subroutines and Ampersands					
Subroutine Prototypes	An older Perl feature. Clashes with subroutine signatures as of Perl v5.20. In Perl >= v5.20 put the :prototype attribute before subroutine prototype parenthesis.							
Subroutine signatures	Exactly zero arguments	()	Zero or 1 argument, no default, unnamed:	(\$=)				
Perl >=5.36: StablePerl >= 5.20:	Zero or 1 argument, no default, named	(\$val=)	Zero or 1 argument, named, with default	(\$val=1)				
Experimental See: Use v5.20	exactly 1 named argument:	(\$val)	Exactly 2 arguments	(\$v1, \$v2)				
subroutine signatures	2, 3 or 4 arguments no defaults: (\$v1,	\$v2, \$=, \$=)	2,3 or 4 arguments, 1 default:	(\$v1, \$v2, \$v3='a', \$=)				
	Two or more, any number of arguments.	(\$v1, \$v2, @)	Two or more arguments, remainders into a named array:	(\$v1, \$v2, @rest)				
	Two or more arguments: an even number	(\$v1, \$v2, %)	Two or more arguments, remainders into a named hash:	(\$v1, \$v2, %rest)				
	Class method	(\$class,)	Object method	(\$self,)				
Returned value	 The result of the last evaluated expression is implicitly returned The return operator can be used but it's not required unless used to change execution flow (return immediately from the subroutine). The subroutine can return a scalar in scalar context or a list if called in list context. Inside the subroutine, use the <u>wantarray</u> function to determine the context of the subroutine call. 							

Perl 5 Modules 🚧

	i dir dimodulos						
Perl Modules							
Perl core modules	• How to detect where a module is installed : perldoc -1 Module • How to check if a module is part of Perl core : corelist Module (Perl >= v5.9.2)						
Access to Modules	Provide access to modules in your code with one of the following: do , require or use						
Modules @perltutorial Modules Using simple modules O	Looks for the module file by searching the @INC path. Performed at run time (and therefore can be done conditionally). If Perl finds the file, it places the code inside the calling program and executes it. Otherwise, Perl will skip the do statement silently. The "included" code does not have access to the lexical variables from the main program. Skip the @INC path lookup if given a file path starting with ./,/, or /						
	Loads the module file once, also searching the <u>@INC</u> path. Performed at run time (and therefore can be done conditionally). • If the require for the same file appears twice, Perl ignores it. Perl will issue an error message if it cannot find the file (as opposed to <u>do</u>). • Skip the <u>@INC</u> path lookup if given a file path starting with ./,/, or /						
The <i>normal</i> way to access Perl modules ➡	Similar to require except that Perl applies it before the program starts: it's done at compile time . Modify it dynamically in a BEGIN block. See IntPo . • Therefore the <u>use</u> statement cannot be invoked inside conditional statements such as if-else. Used often to include a module in a program. That imports the defaults as defined by the module's code. Select what to import with one of the two equivalent forms: (See IntPo): • <u>use</u> Module::Name ('function_a', 'function_b'); • <u>use</u> Module::Name <u>qw</u> (function_a function_b); • <u>use</u> Module::Name (); # import nothing. All accesses to the module must be done with Module::Name::something						
Error handling for: Can't locate in @INC How to fix that See Also: IntPo See: show-perl-inc @ USRHOME	For the above statements to work Perl must be able to identify the location of the requested module(s). • Perl looks for a module code inside the directories identified by the eline array. if you have. use The::Module; inside your code, Perl looks for a sub-directory named 'The' containing a file named 'Module.pm' inside each eline directory. If Perl does not find it, there are multiple ways to solve the problem : • Add the required directory to the list of directories identified in the ':' separated list in the PERL5LIB environment variable. (use ';' as separators in Windows). • Add a use lib 'path/to/the/directory'; statement inside your Perl file to add the required directory when executing a specific piece of Perl code, at compile time. • Run Perl with the lic:capitali option to run the code with the extra directory added to @INC array. To List the directories used by Perl from one of the following equivalent command lines: • perl -e 'print join("\n", @INC), "\n";' • perl -le 'print for INC';' You can also get more information with perl -V						
Specially Named Blocks	5 specially named blocks are run at the beginning or end of a running program: BEGIN , UNITCHECK , CHECK , INIT and END . See: <u>BEGIN block - running code during compilation</u> . Note the <u>security risk warnings</u> . The <u>BEGIN block is used to implement other Perl functionality</u> .						
Declare packages	In Perl a package can span several files and one file may contain the code of several packages. The package starts with the package keyword. The special package literal contains the name of the current package.						

Topic: Data Introspection

Data Introspection								
Using Perl Debugger	Debug a pr	ogram:	perl -d program	_name	program_args			
Debugger Tutorial	Debug inte	ractive session:	perl -d -e 0	perl -d -e 0				
Debugger commands	q	Quit debugger		s	single step			
	h	help. List all availa	ble commands.	x	evaluate expression			
Modules for Data introspection	<u>Data::Dumper</u> (Perl >= 5.005)			that o	nodule provides the Dumper function that prints strings can be used by eval to rebuild the data. It is similar to the x command of the debugger. It is series reference to the variables, otherwise it extends them to and show each entry as its own variable.	print Dumper(\@array);print Dumper \%hash;		
	Data::Dump (Requires Perl >= v5.6.0)			comp	des a dump function that has nicer output, but is not eval artible. mp() prints on the stdout. No need to use print.	use Data::Dump qw(dump); dump(\@array); dump(\%hash);		
	Data::Printer			A nicer data dumper, not <u>eval</u> compatible. It provides the p subroutine that does not require a reference to the variable as it inspects it first. p() prints on the stdout. No need to use print.		use Data::Printer; p(@array); p(%hash);		
Modules for <u>Data Marshalling</u> • <u>Data Serialization in</u> <u>Perl</u>	There are several modules, either part of Perl core or outside, that provides mechanism to marshall/serialize and unmarshall/de-serialize data. • See the links at left for more info.							

Topic: Directory Operations

			· ·		
Directory Operations	In Books: LPo				
Opening Files	All file open operations are relative to the <u>current working</u> relative file names)	ng directory (for	open my \$filehandle, '<:utf8', 'a_relative/path.txt'		
Creating temporary files	File::Temp (Perl >= v5.6.1). <u>Using File::Temp</u> • Also see <u>IO::File</u>				
Built-in Functions	Related Functions/Packages / Descriptions		Notes		
Getting file names by: Globbing: with glob	File::Glob (Perl >= v5.6.0) - provides more control.	Example:	<pre>my @all_files = glob '*'; my @perl_files = glob '*.pm *.pl'; # 2 globs, space-separated</pre>		
with the glob operator <>	The <> operator is identifying: • a filehandle, when: the item inside <> is a Perl identifier or an indirect file handle read scalar, • a glob expression otherwise.		<pre>my @all_files = <'*'>; my @all_files = <*>; # 1 glob: no space, no need for string my @perl_files = <'*.pm *.pl'>; # 2 globs, space-separated</pre>		
operator V			<pre>my \$etc_dir = '/etc'; my @etc_dir_files = <\$etc_dir/* \$etc_dir/.*>;</pre>		
			my @files = <larry *="">; # a glob</larry>		
	See: <u>readline</u>	Filehandle	<pre>my @his_lines = <larry>; # a filehandle read</larry></pre>		
		examples:	<pre>my \$name = 'LARRY'; my @his_lines = <\$name>; # indirect filehandle read of LARRY handle my @same_lines = readline LARRY; # another way to write above my @same_lines = readline \$name;</pre>		
 with a directory handle LPo 	opendir: open a directory: get a directory handle readdir: read the directory handle. But see this. closedir: close the directory handle. DirHandle (Perl <= 5.5) File::Spec::Functions (Perl >= v5.5.4) Path::Class	Example: iterate explicitly over a list of file names extracted from the directory using these 3 functions.	<pre>my \$dir = '/usr/bin'; opendir my \$dh, \$dir or die "Failed opening \$dir: \$!"; foreach \$file (readdir \$dh) { print "File \$file is inside \$dir\n"; # 1 no path in name! } closedir \$dh;</pre>		
Creating directory	• mkdir	Example:	<pre>mkdir \$dir_name, oct(\$permissions); # octal for permissions mkdir \$dir_name, 0700; # do not use "0700", it's 700 decimal!</pre>		
Removing directory	rmdir Removes an empty directory. File::Path remove tree , rmtree remove dir & files (Files remove dir & files (Files remove dir & files remove dir & files (Files remove dir & files remove dir &	Perl >= v5.0.1)			
Removing files	• unlink a list or \$_		<pre>unlink 'file1.txt', 'file2.txt'; unlink qw(file1.txt file2.txt); unlink glob 'file?.txt'</pre>		
Renaming files	rename an old file name to a new one. The fat comma operator is sometimes used to highlight what is the old and the new name.	As in here:	<pre>rename 'old_name' , 'new_name'; rename old_name => 'new_name'; # use fat comma to quote word left of it.</pre>		
Changing permissions	chmod changes file permissions				
Changing ownership	chown changes file ownership				
Creating Hard link	link to create a hard link				
Creating symbolic link	symlink to create a symbolic link				
chdir Change current working directory	File::chdir File::HomeDir	• chdir without \$ENV{LOGDIR	argument attempt to change to user home directory using the \$ENV{HOME} and element values if they are set. The File::HomeDir module helps in setting them. dir is global for the entire program. Use File::chdir facilities for localized operations.		
Modules	Functions Legend: Exported by default, exported on request, W.	in32 specific	Extra Information		
Cwd	getcwd, cwd, fastcwd, fastgetcwd, getdcwd abs_path, realpath, fast_abs_path	<pre>use Cwd; my \$curdir = getcwd; print "cwd is \$curdir\n";</pre>			
File::Basename	fileparse, basename, dirname,				
File::Spec File::Spec::Functions	functional interface to methods: canonpath, catdir, splitpath, splitdir, catpath, abs2rel, rel2abs. All can be		otdir, updir, no upwards, file name is absolute, path. devnul, tmpdir, case tolerant, ng the :ALL tag.		
File::Find : Traverse a directory tree. See: File::Find::Closures	find, finddepth, %options. In wanted: File::Find::dir, Note that \$_gets the base name of the file (no path). It perform filetest operations in the example here (as expl -s, and implicit argument to -d and -f). This traverses the	is used to icit argument to	<u>find</u> (sub {printf("- %-10s : %4d, %s\n", <u>\$_</u> , -s <u>\$_</u> , <u>File::Find::name</u>)		

Topic: List Operations

List Operators								
Sorting lists	sort	Sort a list	<pre>my @sorted = sort @unsorted_list;</pre>	in place: my @data = sort @data;				
	reverse	Sort a list in reverse order	my @rsorted = <u>reverse</u> @unsorted_list;	in place: my @data = <u>reverse</u> @data;				
Filtering list with grep	my @adult_	ages = grep \$_ > 18, @ages;	my @lucky_ages = grep /7\$/, @ages; # all that end with 7	my @read_ages = grep { \$_ >= 7 && \$_ <= 77 } @ages;				
Counting matches	my \$count	= grep \$_ > 18, @ages;						
		An expression, subroutine or block with trailing boolean can be used as the grep criteria. Each item in the list is identified inside grep by \$ The block is an anonymous subroutine.						
Transform a list with map								

Topic: Process control

Topic: Process control					
Process Control	In Books: LPo Important security information: peridoc perisec				
Environment Variables	Inside the <u>%ENV</u> hash. Perl <u>%Config</u> hash. • To use it: us		ash: Perl configuration information. For example, whether it support threads, what are path separators, etc se Config;		
Built-in Functions	Example		Description/ Notes		
• using the shell • security risk?	<pre>system 'ls -1 \$HOME';</pre>		Run child process asynchronously using parent's stdin, stdout and stderr, using the OS native command shell.		
	<pre>system "cd \$project; make &";</pre>		Use the Unix shell to execute a long running build asynchronously. However: avoid using the shell like this. • Using the shell to build commands from unvalidated user input data may lead to security issues.		
avoiding the shell	system 'tar', 'cvf', \$tarfile, @directories;		No shell invoked when more than 1 argument is passed to system. No shell interpretation, piping, re-direction done.		
 other syntax 	system('tar', @arguments);		0 means success: unless (system 'tar', arguments) { print "tar command success\n"; }		
	<u>system(</u> { \$prog }, \$arg0, @args);				
	Solution Note that if the string contain no shell metacharacters it is executed directly (not through a shell).				
 system return value: A value of 0 usually means all was OK. 	2 bytes: MSByte: child pro	gram exit code.	<pre>my \$retval = system();</pre>		
	LSByte: system-specific information bits: • 0x80 : set on core dump. • 0x7f : signal number		my \$childp_exitcode = \$retval >> 8;		
exec	Unlike system, exec does not return to the parent Perl process. Use: exec 'the_program' or die "Could not run: \$!"; #or warn or exit				
backquotes``	Use backquotes to capture the trailing newline is not fill		gram. That's the main point of using it. e filter by <u>chomp</u> .	<pre>chomp(my \$current_date = `date`);</pre>	
	invoke the shell if there are a • The following example bu • Note that `` is also written	any shell meta-cha uilds a dictionary (n as qx/ /	e the single double quote string argument of system: it will aracters and supports interpolation. hash) of topics with the text extracted from peridoc. 1 string. In list context it returns a list of strings (1 per line).	<pre>my @topics = qw(die warn exit); my %info; foreach (@topics) { \$info{\$_} = `perldoc -t -f \$_`; }</pre>	
Modules					
Capture streams	<u>Capture::Tiny</u>	Can be used to	capture the stdout and stderr streams for various ways if exe	ecuting other programs	
Inter-process support			d to capture streams and provide more inter-process suppor stemx which never uses the shell, along with other useful fur		
Processes as filehandles	In Books: LPo				
Perl - program	Launching a process that pipes into the Perl process	open DATE, 'dat	te or die "Cannot pipe from date: \$!";	Use a bare word to define the DATE file handle.	
		open my \$date_	fh, '- ', 'date' or die "Cannot pipe from date: \$!";	This one and the others define a local file handle variable. The file handle variable can later be used to read, as the	
		open my \$ps_fh	, '- ', 'ps', 'aux' or die "Cannot pipe from ps: \$!";	above one, but is not global.	
		open my \$find_f	open my \$find_fh, '- ', 'find', qw(name '*.p[lm]' -print) or die "Cannot pipe from find: \$!";		
Perl ➡ program	Launching a process that the Perl process pipes into.	open my \$dispa	ther_fh, ' -', 'dispatcher', qw ('-to-perl-groups' 'Help!') or o	die "Cannot pipe to the dispatcher: \$!";	
Forking	In Books: LPor. See also: Linux fork(2) system call, QA: Why do we need fort to create new processes? Why fork woks the way it does?				
fork with exec and waitpid See also: Other IPC functions Perl IPC	fork the process into parent and child. in the child process start the program with exec In the parent process wait for the program termination with waitpid	<pre>unless (\$pro # Inside t exec 'long }</pre>	he child process (created by fork) _running_process' or die "Failed starting lor parent process, wait for completion of long_		
Signals	In Books: LPor				
kill	Sends a signal to a list of processes. • The signal may be identified by number or name (string), which is more portable. • The \$\frac{\text{kill}}{\text{config{sign_name}}}\$ provides the supported signal names.				
	Note that the fat comma operation.	erator (=>) can be	used to automatically quote signal name:	kill INT => \$pid or die "Can't signal \$pid with SIGINT: \$!";	
	If the signal is 0 or "ZERO" r signal to the process: ie: if the signal to the process: ie: if the signal is 0 or "ZERO" representations of the signal		o the process; instead Perl checks if it's possible to send a	unless (kill 0, \$process_id) { warn "Process \$process_id is no longer running!"; }	
	If the signal is a negative nuited identified by the process scale.		nat starts with '-' the signal is sent to the process group	• <u>kill</u> '-KILL', \$process_group • <u>kill</u> -9, \$process_group	
<u>Signal handlers</u>	• Set the signal handler by setting %SIG for the signal name (with no 'SIG' prefix) to a string holding the name of the subroutine. \$\sigma \left[\sigma \right] \text{ int_handler';}				

PerlTidy formatting control

perItidy option	Option	Impact	
indentation style	bl,opening-brace-on-new-line - brace left	 Without this option (the default) the code indentation style selected is <u>K&R style</u>. With this option, the indentation style is <u>Allman/BSD style</u>.
