## **Terminal Key Sequence Settings & Tools For investigation**

Application	Туре	Description						
macOS Tools	The following tools to investigate the keyboard behaviour in macOS terminal emulators and the OS in general are listed in this table.							
Character Viewer	Builtin macOS Application	Used to get printable symbols that represent keys. Also see this Penn State site about Symbols and Characters.Å						
Key Codes	Third party macOS Application	Used to get Unicode key codes for the keyboard key pressed. Accessible via App Store Developer Tools.						
macOS Terminal	Builtin macOS Application	<ul> <li>Type ^V followed by the key in terminal to display the character sequence sent to the application for this key.</li> <li>Use the Terminal Profiles, section Keyboard to add key mappings. The new mappings are available in the current terminal. If the mapping exists in Emacs it takes affect in Emacs as well. Both profiles are available as different bash shells in Terminal.app</li> <li>Note that in Terminal, you can use **C-o to toggle the meaning of the *C (Alt) key between Meta and 'alternate character'.</li> </ul>						
iTerm2	Third party macOS Application	<ul> <li>Type ^V followed by the key in terminal to display the character sequence sent to the application for this key. Used to check for codes that are not sent in terminal, so we can add them to iTerm2 Profiles Keyboard mapping.</li> <li>In iTerm2, the left \(\times\) (Alt) key can be configured as Meta, the right \(\times\) (Alt) key can be used as 'alternate character'.</li> </ul>						

Use the Terminal Preference dialog, in the Profiles section, then in terminal, to identify extra key codes for missing keys in the Terminal.App terminal emulator.

The following screenshot is an example of the dialog.

The table below shows all codes I was able to configure for the macOS Terminal.app in macOS 10.14.6 (Mojave).

^ <b>企F20</b>	\$^F717			No		No		
<b>∀</b> ←		\033b \033Y		Replace		Replace		This original key sequence here is \033b However this keys sequence is problematic: \033b corresponds to "Esc b" which is translated to M-b by Emacs. • The consequence is that it becomes impossible to distinguish M-b from M- <left>. • PEL provides a work-around to allow terminal to distinguish M- b from M-<left>: set the pel-map-meta-left-right-to-Y- Z user-option on so that PEL expects M-Y for the commands that are supposed to be mapped to M- <left>. Then setup the terminal profile to generate \033Y. • The M-Y key sequence was selected because it is not normally used and also because the M-Y key sequence does not use the Shift marking concept.</left></left></left>
^←		\033[1;5D	^[[1;5D	Yes		No need		
<b>ዕ</b> ←		\033[1;2D		Yes		No need		Supported: does shift-select on corresponding unshifted keys
^∵←		\033[1;7D		Yes		Yes		
<b>→</b> ☆ブ^		\033[1;8D		Yes		Yes		Supported: does shift-select on corresponding unshifted keys.
→☆ブ		\033[1;4D		Yes		Yes		Supported: does shift-select on corresponding unshifted keys.
^☆←		\033[1;6D		Yes		No need		Supported: does shift-select on corresponding unshifted keys
\tag{\tau}		\033[1;3A		Yes		Replace		iTerm2 default profile maps ℃↑ to sending 0x1b 0x1b 0x5b 0x41 with corresponds to Esc Up. In PEL we want to distinguish Esc Up from Meta Up. Therefore PEL changes the mapping here.
^↑		\033[1;5A	^[[1;5A	Yes		No need

## Terminal Emulator Concepts — References

Topic & Link	Description and Notes
Background Information	The first list of references provide the knowledge on character encoding and escape sequence used by terminal emulators required to understand the way keys are encoded and the limitations of terminal emulators. Understanding this is required if one which to understand the various proposals for "lossless keyboard input" for terminal emulators.
Wikipedia - ASCII simple	A quick overview of what ASCII standard is. The <u>ASCII table</u> shows the control codes in the first column. Those control codes are called Control- <i>x</i> where <i>x</i> is the character shown in the third column of the table. Which makes Ctrl-@, CTRL-A up to Ctrl Note that has historically been type by holding the Control key and the key A, without holding the Shift key.
Wikipedia - ASCII	More complete description of the ASCII standard and its history.
Wikipedia - ANSI escape code	The basis of terminal emulator software taking information from typed keys is the ANSI <u>escape sequence</u> codes, more specifically the CSI sequences. This page explains the overall concepts and their history.  Note the following:  • The <b>ESC</b> ASCII character is value 27 (base 10), which is 033 octal and 0x1B hexadecimal.  • All <b>escape sequences</b> start with ESC followed by a second byte in the range 0x40-0x5F (ASCII <b>@A-Z[\]^_)</b> .  • This is the same range of characters selected to represent control characters.  • That represent a total of 32 escape sequences.  • This 2 byte sequence can be replaced by a single byte, but we can't use that now: it clashes with UTF-8 values.  • The <b>CSI</b> (Control Sequence Introducer) is a sequence of several bytes:  • starting with <b>ESC</b> [  • followed by any number (could be none) of parameter bytes in the range 0x30-0x3F (ASCII <b>0-9:</b> ;<=>?)  • sequences containing the parameter bytes <=>? are considered "private" to the manufacturer.  • followed by any number of <i>intermediate bytes</i> in the range of 0x20-0x2F (ASCII <b><space></space></b> and <b>!</b> "#\$  *&'()*+,/)  • ending with a <i>final byte</i> in the range 0x40-0x7E (ASCII <b>@A-Z[\]^</b> _1^_a- <b>z</b> _{{ }}-)  • final byte in the range 0x70-0x7E ( <b>p-z</b> { }-) are private.
Wikipedia - Unicode range 0000-0FFF	The Unicode range 0000-0FFF holds all letters, numbers and punctuation available on US and most European keyboards. Those values, augmented with modifier keys can be used to represent values normally not supported by terminal emulators, such as C-S-a and C-` (which do not correspond to ASCII control characters).
Wikipedia - Unicode range E000-F8FF used as private use area	The macOS Unicode value for the cursor and function keys are in 0xF700 - 0xF72F range, which makes them part of the "private use area".
Limitations of Terminal Emulators and improvement proposals	
3000	TODO
Packages providing Lossless Keyboard Input	
Editing Property Lists with plutil	macOS provides the plutil command line utility to test, read, convert and modify macOS Property list files, like the file ~/Library/Preferences/com.apple.Terminal.plist which contains all Terminal.app preferences.  This is the file that needs to be modified to add key bindings, you can use the instructions in term-keys.el package (see below) to do so.  A Before modifying the file with plutil, make a backup copy, in case something goes wrong!
Github - term-keys - lossless keyboard input for Emacs	This package allows creating binding to several keys that are not available to Emacs running inside a text (termcap) terminal emulator process. For example, the C-` and C-/ key-chords are normally not accessible in terminal mode, simply because these do not correspond to ASCII control character values.  • The term-key package can build the list of translation codes to make these key-chords accessible in terminal-base Emacs. The mechanism used is specific to the terminal emulator software, and several terminal emulators are supported, including the macOS Terminal.app.  • Term-key uses a byte sequence prefix that is used for all the extra key definitions. To be able to bind the new keys in Emacs the prefix used by term-key must not be already used in any Emacs binding.  • The default (but customizable) prefix is "\033\037" which corresponds to ESC C which is C-M binding in Emacs, that used to not be bound to anything until Emacs 28 with bounds it to undo-redo.  The term-keys.el readme describes how to make modifications to the Terminal.app Property to support new keys for Emacs. See the macOS Terminal section of the file (A make a backup of the file first!).  • To edit a macOS plist file, use the open command from the shell. It will open the plist file inside Xcode.
