### Perl scripts

Writing Perl scripts	npose strictures in Perl files to prevent errors by adding one of the following use lines. Also see the strictures package.					
Use the following at the beginning of Perl script files.  perldiag @ perldoc	<pre>#!/usr/bin/env perl use strict; use warnings;  # for testing only: use diagnostics;</pre>	#! /usr/bin/perl -w use v5.12; # loads strict use v5.35; # &loads warnings  use diagnostics produces more info but increases startup time.  Alternative: perl -Mdiagnostics . Emacs p	Executable Perl script should have a valid shebang line identifying the appropriate location of the Perl interpreter. It may have to be modified at installation time (OpenGroup/SUS).  It's best to: use warnings; perl -w generates warning for all Perl code in the program including modules used by the program. Also use the _c option to check syntax. But most Perl code should also activate the strict Perl rules and warnings to detect warnings. See: Barewords in Perl  perl-critic command can report diagnostic.			
use version/features	<u>use</u> v5.36;		This can be used to enable both the strict and warning pramas as well as several <u>named features</u> .  • See the <u>table listing the feature bundles per Perl versions</u> .

Perl 5 Operators
Perl 5 Operators
                             Perl operators, listed below with their precedence and associativity.
                                                                                                                                             C Operators missing from Perl: unary &, unary * and (type)
                   Note:
                             • Quote and Quote-like operators: in Perl quotes are operators and they provide various kind of interpolating and pattern matching capabilities
Associativity: one of:
                             left
                                          terms and list operators (leftward)
                                                                                                                                        Note: print, sort, reverse, chmod, are list operators
  right
                             1eft
                                          Arrow Operator:
  left
                             NA
                                          Auto-increment and Auto-decrement: ++ --
• NA : not associative:
                             right
                                          Exponentiation:
  cannot use more than one of these operators
                             right
                                          Symbolic Unary Operators:
                                                                                     1 ~
                                                                                            -. \ and unary + and -
                                                                                                                                         Note: The operator \ creates a reference. See example.
                             left
                                          Binding operators:
   in sequence.
                             left
                                                                                     * /
                                                                                            %
                                          Multiplicative Operators:
                                                                                                  x

    CH: chained

                             left.
                                          Additive Operators:
                             left
                                                                                            >>
                                         Shift Operators:
                                                                                     <<
                             NA
                                          named unary operators

                                          Interpolate an array in a string:
                                                                                                           print "these people @{[get_names()]} get promoted"
                             @{[]}
operators; they are
                                          the same as:
concatenation of other
                                         Force scalar context.
                                                                                In scalar context localtime returns human readable time.
operators that achieve a
                                                                                                                                                      $ perl -le 'print ~~localtime'
                                                                                but in list context it returns a 9-tuple with date elements.
                                                                                                                                                        on Nov 30 09:06:13 2009
specific effect.

    Negation of a true value by "!" or "not"

Truth and falsehood
                             False in a boolean context:
                                                                                                          These scalar values are false:
                                                                                                                                                      All other scalar values are true, such as:
                                                                returns a special false value.

When evaluated as a string it is
                                                                                                             undef - the undefined value
                                                                                                                                                        1 and any non-0 number
                               • the number \mathbf{0},
1 The strings '0' and '
                               • the strings '0' and ' '.

    0 the number 0, even if you write it

                                                                                                                                                          ' the string with a space in it
mean false. The output
                                                                treated as ", but as a number, it is treated as 0.
                                                                                                                                                      • '00' two or more 0 characters in a string
                                                                                                             as 000 or 0.0
                                  the empty list ().
of glob() may return a file

"0\n" a 0 followed by a newline
'true'. 'false' . Even 'false' evaluates to true.

                                                                                                               the empty string.
                                  "undef
named '0'!
                                                                                                           • '0', a single 0 in the string.
1 The bareword false
                              All other values are true.
                                                                                                                                               use constant { true => 1, false => 0 };
has a truth value of true!
                             🤞 One way to define valid true and false constant symbols that can be used in assignments (but see 🗢):
                                                                                                                                                if (-e $fname && -f _ && -r _ ) {
  print("$fname exists, is readable\n"); }
File test operators
                             File tests can be stacked (-r -w -e $fname) or combined as in the following example or:
See filetest -X
                               Notice the underscore in the example: it's the virtual filehandle _ accessing the last stat or lstat result :
                                         is readable by effective uid/gid
                                                                                                                                                      is a block special file.
The operators check if
                                                                                       exists.
                                         is writable by effective uid/gid is executable by effective uid/gid
the file..
                                                                                        is empty
                                                                                                                                                      is a character special file.

                                           local, lexical scope, non persistent
                                                                                          Examples:
                                                                                                          \underline{\mathbf{m}}\mathbf{v} @values = (42, 36, 99); \underline{\mathbf{m}}\mathbf{v} ($v1, $v2) = (42, 36);
Scope of variables in Perl
                              state
                                                                                          Perl >= v5.10
                                                                                                              Restriction: in Perl < v5.28: array and hashes state cannot be initialized in list context.
                                           Local, lexical scope, persistent
@Perl Maven
                                           creates a lexical scoped alias to a package variable
                                           Localizes an existing package variable to the current scope. It's not a declaration. The variable previous value is restored when leaving the scope.
                              local
Perl types
                                                                                                                                    Last index of array @days
                             $foo
                                                   Simple scalar value
                                                                                                               $#days
                              $days[28]
                                                    29th element of array @days
                                                                                                               $days->[28]
                                                                                                                                    29th element of array pointed to by reference $days.
                                                    Value associated with the Feb key of hash %days
                                                                                                                                    Multi-dimensional array
                              $days{'Feb'}
                                                                                                               $days[0][2]
                                                                                                               $d{99}{'Feb'}
$d{99, 'Feb'}
Archaic use of single
                              ${days}
                                                   Same as $days, use before alphanumumerics.
                                                                                                                                    Multi-dimensional hash
auote:
            $Dog'days
                              $Dog::davs
                                                   The $days variable inside the Dog package.
                                                                                                                                    Multi-dimensional hash emulation
list and Array
                                                                                                               • A list is an ordered collection of scalars (of any type).
                         @
                                                Array containing ($days[0], $days[1], ... #days[$#days])
                              @days[3,4,5] Array slices containing ($days[3], $days[4], $days[5])
  0-based indexed (first
                                                                                                                 An array is a variable that contains a list.
  index is 0).
                              @days[3..5] Array slices containing ($days[3], $days[4], $days[5])
                                                                                                               · Reading beyond the end of array returns undef
                              • Negative indices used in read access from the end: -1 is last item
  @name is $#name
                               Use these negative indices to access from the end. Do not compute index with $#name -3, if the list size is 2, this will give invalid results.
                              · Use a slice to select multiple elements from a list, array, or hash.
                                                                                                                                                           mv @diaits = (0..9)
                                                                                                               my @extracted = (6, 2, 8, 4):
· array slices LPo
                                                                                                               my @choices = @digits[@extracted]
my $mod_time = (state $filename)[9];
                                                                                                                                                           my @one2five = @digits[1..5];
    Simple explanation
                             • Don't use a slice when you know you need exactly one element.
                                                                                                                                                          my @premiers = @digit[1, 2, 3, 5, 7];

    An Ivalue slice imposes list context on the righthand side.

                             @extracted[1, 3] = (7, 9);
· Anonymous arrays
                                What are the advantages of anonymous array? @ StackOverflow
                                                                                                               • Anonymous array := a type of array reference. Use it to build nested data structures.

    Array reference allows Perl to treat the array as a single item.

                                Perlref @ Perldoc, Perl reference tutorial @ Perldoc
Hash/associative array
                                           %days
                                                                Associative array (hash): keys-value pairs. Can be initialized as:
                                                                                                                                                    Initialize a hash slice with array context:
                                                                   my %days = (Jan => 31, Feb => $leap? 29 : 28, ...)
my %days = ("Jan", 31, 'Feb', $leap? 29 : 28, ...
                                                                                                                                                    @char_to_num{'A' .. 'Z'} = 1 .. 26;
my %rating = (ron => 20, al => 50, steve => 80);
Hashes @ Perl Maven
Note: keys are always
                                                                    Multiple values of a hash can be changed with the following construct:
                strings.
                                                                                                                                                     # use fat comma to quote word left of it. 9
hash slice LPo
                                                                                                                                                    my @names = ('ron', 'al');

                             print $data->[3]->[3]->[0], "\n";
print $data->[3]->[3]->[0], "\n";
print $data->[3][3][0], "\n";
                                                                                                               • Pass array or hash to subroutine: fct(\@a, \%h); Return from sub: return (\@a, \%h);
• simplify with ->
                                                                                   # 100

    simplify more

    Arrows between subscript are optional.

                                                                                                                                                    • &{ $the_function } (arg1, arg2);
• $the_function->(arg1, arg2);
Reference to subroutine
                                                                my $fct ref = \&the function;
                                                                                                               with the simpler arrow notation:
                                                                                                               Using an anonymous subroutine, always calling it indirectly:
                                                                                                               say $op->(10, 4); # prints 10000
                              A closure binds its environment and keeps it to use it when invoked.
                                                                                                               sub make greeting
Closures
                                                                                                                    make_greeting {
my $greet = shift;
my $greet_fct = sub {
    my $name = shift;
    print "$greet, $name!\n";

    In the example at right, a greeter function is built and returned,
remembering how to greet. It is used like this:

  Perl closure
                                  my $fr = make_greeting("Bonjour");
my $it = make_greeting("Buongiorno");
$fr->('Brigitte'); # prints: "Bonjour, Brigitte!\n"
$it->('Madonna'); # prints: "Buongiorno, Madonna!\n"
                                                                                                                     return $greet_fct; # return ref to internal function
Scalar values
                              Numeric
                                                                    literals examples: Note: leading 0 work only for literals, not for string-to-number conversions.
                                                                                                                                                                               Useful related builtin functions

                                                                                          my $x = 0b1100_0010;
                             (such as dividing 1 by 2).
                                                                                                                              # binary with underlines

    string

                                double-quoted strings: perform backslash and variable interpolation of expression that begin with $ (a scalar) or @ (an array). Hashes cannot be interpolated.
                               single-quote strings: only perform \ ' and \ \ substitution (to ' and \ respectively), nothing else.

Single quote and double quote strings can spread multiple lines: it embeds the newline character on each new line.
                              • \n is only expanded in double quoted strings. In single quote string it is treated as two characters; no substitution is done (as explained above).

    Unicode support

                             Use Unicode literally in a program; add the utf8 pragma: use utf8;
                                                                                                              See: Perl Unicode Tutorial, Perl Unicode Introduction, Perl Unicode Support @ perldoc

Internal UTF-8 offset caching code state	\${^UTF8CACHE}		State of UTF-8 locale detected by perl at startup.	\${^UTF8LOCALE}		
File handle Variables	See also: Perl File Handles	The following var	iables are used in the Input/Output handli	s are used in the Input/Output handling as well as program arguments.		
Name of current file read from <>	\$ARGV	Command line arguments of the so  ← See diamond operator <>.	eript → @ARGV	Number of arguments minus one	\$#ARGV	
Special file handle that iterates over command-line filenames in @ARGV	ARGV	Special file handle that points to currently open output file when do edit-in-place processing	ARGVOUT			
Output field separator for the print operator	• IO::Handle->output_field • \$OUTPUT_FIELD_SEPA • \$OFS • \$,		Current line number for the last file handled accessed	• HANDLE->input_ • \$INPUT_LINE_NU • \$NR • \$.		
Input record separator (newline by default)	• IO::Handle->input_record • \$INPUT_RECORD_SEP. • \$RS • \$/		Output record separator	• IO::Handle->outpu • \$OUTPUT_RECO • \$ORS • \$\	t_record_separator( EXPR ) RD_SEPARATOR	
Auto-flush control    order of output @ Perl    Maven    Suffering from    Buffering?	HANDLE->autoflush( EX     SOUTPUT_AUTOFLUSH     \$I		ult.	\${^LAST_FH}		

## Perl 5 Input/Output

For example:  $|\underline{\text{perl}} \ \underline{-p} \ \underline{-i}^{\sim} \ \underline{-w} \ \underline{-e}$  's/something/Something else/g' data\*.dat

References	open @ peridoc browser     Writing to files with Perl @ P     open file in-memory @ stack		e	<ul><li>print to a string</li><li>read lines from</li></ul>			
print, printf, sprintf		print, printf, sprintf (which describes the format). Note: print, a list operator, is more efficient than printf.  printf output to stdout by default, but accept a file handle as the first argument if it is NOT followed by a separating comma! (a ',' puts it in the list to print!)					
say	use feature qw(say)	use feature qw(say); or use v5.10; (or higher). Like print, but implicitly appends a newline at the end of the list.					
diamond operator <> The double diamond, a	Both <> and <<>> operators read the content of files listed on the command line via @ARGV. Nothing or - on the command line identifies stdin.  The <> operator supports shell redirection and pipe operations which <<>> does not allow (for security reasons).						
more secure <> (Perl >=	print <>;	← Simple implementation of /bin/cat	print <<>>;	← safer one	Redirection cannot be forced via file names embedding them		
v5.22)	<pre>print sort &lt;&gt;;</pre>	← Simple implementation of /bin/sort	<pre>print sort &lt;&lt;&gt;&gt;;</pre>	← safer one	with. the <<>> operator.		
In-place-editing of The <> operator tries to duplicate the original file's permission and ownership.	change the behaviour of the <: In a while (<>) {} loop, w	_	<pre>use strict; \$^I = "~"; # rename old file: add '~' to it's name (Emacs-style backup) while (&lt;&gt;) {     s/something/Something else/; # perform any substitution     print; }</pre>				

perl -i cmdline option

It's also possible to do this on the command line!

Special filehandle	ARGV	The special filehandle that iterates over cor	mmand-line filenames in @ARGV. Usually written as the	he null filehandle in the angle operator <> (or <<>>)			
Also See:	ARGVOUT	The special filehandle that points to the cur  • Useful when you have to do a lot of inser	rrently open output file when doing edit-in-place procerting and don't want to keep modifying \$_	essing with <u>-i</u> .			
<ul> <li>File handle Variables section above.</li> <li>open</li> </ul>	STDIN	**STDIN>: line input operator for the STDIN filehandle (for the standard input).  Each time <stdin> is used in scalar context, Perl reads 1 complete line of the standard input and uses it as the value of <stdin>.  • The string includes a line termination character. Use the chomp built-in function to strip it off the variable.  If <stdin> is read in list context, it returns all lines inside a list! For example, foreach (<stdin>) { } reads the entire stdin in 1 step: \$_ holds it all!</stdin></stdin></stdin></stdin>					
		<pre>while (<stdin>) { # print all     print; # lines of } # stdin</stdin></pre>	<pre>while (defined(\$_ = <stdin>)) {    print \$_; }</stdin></pre>	The code in the left-most cell is the shortest form. It is equivalent to the code beside it; each line of stdin is stored in the default variable \$_ and the loop stops on end at which time <stdin> returns undef.</stdin>			
	STDOUT	standard output					
	STDERR	v	R is not buffered, while STDOUT is buffered by defaul TDOUT to help flushing it or assign 1 to \$   to activate	It. Text sent on STDERR may show up before STDOUT. e auto-flush.			
	DATA						

To get information about a Perl function from the command line use the **perldoc -f** command.

 Takes advantage of a block value is the value of the last expression executed inside the block. Do \*not\* return from the block. • The last, next and redo cannot be used inside do blocks.

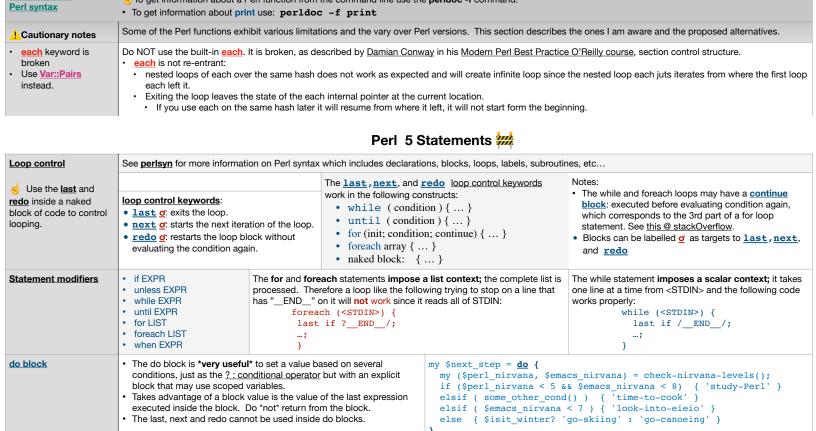

Perl Functions

Compound statements

?: conditional operator

if, elsif, else

#### Perl 5 Built-in Functions ##

### Perl 5 Subroutines ##

Perl subroutines				
subroutine &	Why we teach the subroutine ampersand     Why should I use the & to call a Perl subrouting	e? @ StackOverflow	Another point of view: <u>Subroutines and Ampersands</u>	
Subroutine Prototypes	An older Perl feature. Clashes with subroutine sign	gnatures as of Perl v5.20	. In Perl >= v5.20 put the :prototype attribute before sub	routine prototype parenthesis.
Subroutine signatures	Exactly zero arguments	()	Zero or 1 argument, no default, unnamed:	(\$=)
<ul><li>Perl &gt;=5.36: Stable</li><li>Perl &gt;= 5.20:</li></ul>	Zero or 1 argument, no default, named	(\$val=)	Zero or 1 argument, named, with default	(\$val=1)
Experimental See: <u>Use v5.20</u>	exactly 1 named argument:	(\$val)	Exactly 2 arguments	(\$v1, \$v2)
subroutine signatures	2, 3 or 4 arguments no defaults: (\$v1,	\$v2, \$=, \$=)	2,3 or 4 arguments, 1 default:	(\$v1, \$v2, \$v3='a', \$=)
	Two or more, any number of arguments.	(\$v1, \$v2, @)	Two or more arguments, remainders into a named array:	(\$v1, \$v2, @rest)
	Two or more arguments: an even number	(\$v1, \$v2, %)	Two or more arguments, remainders into a named hash:	(\$v1, \$v2, %rest)
	Class method	(\$class,)	Object method	( \$self,)
Returned value	The result of the last evaluated expression is in The return operator can be used but it's not re The subroutine can return a scalar in scalar cc Inside the subroutine, use the wantarray fully	equired unless used to chontext or a list if called in		).

## Perl 5 Modules **##**

Perl Modules						
Perl core modules	• How to detect where a module is installed : perldoc -1 Module • How to check if a module is part of Perl core : corelist Module (Perl >= v5.9.2)					
Access to Modules	rovide access to modules in your code with one of the following: do, require or use					
Modules @perltutorial Modules Using simple modules or	Looks for the module file by searching the <code>@INC</code> path. Performed at run time (and therefore can be done conditionally).  If Perl finds the file, it places the code inside the calling program and executes it. Otherwise, Perl will skip the do statement silently.  The "included" code does not have access to the lexical variables from the main program.  Skip the <code>@INC</code> path lookup if given a file path starting with ./,/, or /					
	Loads the module file once, also searching the <u>@INC</u> path. Performed at run time (and therefore can be done conditionally).  • If the require for the same file appears twice, Perl ignores it. Perl will issue an error message if it cannot find the file (as opposed to <u>do</u> ).  • Skip the <u>@INC</u> path lookup if given a file path starting with ./,/, or /					
The normal way to access Perl modules ➡	Similar to require except that Perl applies it before the program starts: it's done at compile time. Modify it dynamically in a BEGIN block. See IntPor.  • Therefore the use statement cannot be invoked inside conditional statements such as if-else. Used often to include a module in a program. That imports the defaults as defined by the module's code.  Select what to import with one of the two equivalent forms: (See IntPor):  • use Module::Name ('function_a', 'function_b');  • use Module::Name qw( function_a function_b );  • use Module::Name (); # import nothing. All accesses to the module must be done with Module::Name::something					
Error handling for: Can't locate in @INC How to fix that See Also: IntPo See: show-perl-inc @ USRHOME	For the above statements to work Perl must be able to identify the location of the requested module(s).  • Perl looks for a module code inside the directories identified by the @INC array.  if you have. use The::Module; inside your code, Perl looks for a sub-directory named 'The' containing a file named 'Module.pm' inside each @INC directory.  If Perl does not find it, there are multiple ways to solve the problem:  • Add the required directory to the list of directories identified in the ':' separated list in the PERL5LIB environment variable. ( use ';' as separators in Windows).  • Add a use 1ib 'path/to/the/directory'; statement inside your Perl file to add the required directory when executing a specific piece of Perl code, at compile time.  • Run Perl with the -I (capital i) option to run the code with the extra directory added to @INC array.  To List the directories used by Perl from one of the following equivalent command lines:  • perl -e 'print join("\n", @INC), "\n"; '					
	• perl -le 'print for INC';'  You can also get more information with perl -V					

## Topic: Data Introspection

Data Introspection									
Using Perl Debugger	Debug a program: perl -d program			_name	_name program_args				
Debugger Tutorial	Debug inte	eractive session:	perl -d -e 0						
Debugger commands	q	Quit debugger		s	single step				
	h	help. List all availa	able commands.	x	evaluate expression				
Modules for Data introspection	<u>Data::Dumper</u> (Perl >= 5.005)		The module provides the Dumper function that prints strings that can be used by <a href="eval">eval</a> to rebuild the data. <ul> <li>It is similar to the x command of the debugger.</li> <li>Pass reference to the variables, otherwise it extends them to list and show each entry as its own variable.</li> </ul>		<pre>• print Dumper(\@array); • print Dumper \%hash; to</pre>				
	Data::Dump (Requires Perl >= v5.6.0)		comp	des a dump function that has nicer output, but is not <u>ev</u> patible. mp() prints on the stdout. No need to use print.	al use Data::Dump qw(dump); dump(\@array); dump(\%hash);				
	Data::Printer		A nicer data dumper, not <a href="eval">eval</a> compatible.     It provides the <a href="p">p</a> subroutine that does not require a reference to the variable as it inspects it first.     p() prints on the stdout. No need to use print.		use Data::Printer; p(@array); p(%hash);				
Modules for Data Marshalling Data Serialization in		several modules, eit links at left for more		re or o	utside, that provides mechanism to marshall/serialize an	d unmarshall/de-serialize data.			

#### Topic: Directory Operations 🚧

		Topic: D	Pirectory Operations 🚧
<b>Directory Operations</b>	In Books: LPo		
Opening Files	All file open operations are relative to the <i>current workin</i> relative file names)	ng directory (for	open my \$filehandle, '<:utf8', 'a_relative/path.txt'
Creating temporary files	File::Temp (Perl >= v5.6.1). <u>Using File::Temp</u> • Also see <u>IO::File</u>		
Built-in Functions	Related Functions/Packages / Descriptions		Notes
Getting file names by:  Globbing:  with glob	File::Glob (Perl >= v5.6.0) - provides more control.	Example:	<pre>my @all_files = glob '*'; my @perl_files = glob '*.pm *.pl'; # 2 globs, space-separated</pre>
with the glob	The <> operator is identifying:  • a filehandle, when: the item inside <> is a Perl identifier or an indirect file handle read scalar,  • a glob expression otherwise.	Glob examples:	<pre>my @all_files = &lt;'*'&gt;; my @all_files = &lt;*&gt;; # 1 glob: no space, no need for string my @perl_files = &lt;'*.pm *.pl'&gt;; # 2 globs, space-separated</pre>
operator <>	a glob expression otherwise.		<pre>my \$etc_dir = '/etc'; my @etc_dir_files = &lt;\$etc_dir/* \$etc_dir/.*&gt;;</pre>
			my @files = <larry *="">; # a glob</larry>
	See: readline	Filehandle examples:	<pre>my @his_lines = <larry>; # a filehandle read</larry></pre>
			<pre>my \$name = 'LARRY'; my @his_lines = &lt;\$name&gt;; # indirect filehandle read of LARRY handle my @same_lines = readline LARRY; # another way to write above my @same_lines = readline \$name;</pre>
with a directory handle     LPo	opendir: open a directory: get a directory handle     readdir: read the directory handle. But see this.     closedir: close the directory handle.     DirHandle (Perl <= 5.5)     File::Spec::Functions (Perl >= v5.5.4)     Path::Class	Example: iterate explicitly over a list of file names extracted from the directory using these 3 functions.	<pre>my \$dir = '/usr/bin'; opendir my \$dh, \$dir or die "Failed opening \$dir: \$!"; foreach \$file (readdir \$dh) {    print "File \$file is inside \$dir\n"; # A no path in name! } closedir \$dh;</pre>
Creating directory	• mkdir	Example:	<pre>mkdir \$dir_name, oct(\$permissions); # octal for permissions mkdir \$dir_name, 0700; # do not use "0700", it's 700 decimal!</pre>
Removing directory	rmdir Removes an empty directory.     File::Path remove tree , rmtree remove dir & files (Files).	Perl >= v5.0.1)	
Removing files	unlink a list or \$		<pre>unlink 'file1.txt', 'file2.txt'; unlink qw( file1.txt file2.txt); unlink glob 'file?.txt'</pre>

Renaming files	Tename an old file name to a new one. The fat comma operator is sometimes used to highlight what is the old and the new name.	As in here:	rename 'old_name' , 'no rename old_name => 'no	
Changing permissions	<u>chmod</u> changes file permissions			
Changing ownership	chown changes file ownership			
Creating Hard link	<u>link</u> to create a hard link			
Creating symbolic link	<u>symlink</u> to create a symbolic link			
chdir Change current working directory	File::chdir     File::HomeDir	• chdir without \$ENV{LOGDIF	a) environment values if 🛕 they ar	ser home directory using the \$ENV{HOME} and re set. The File::HomeDir module helps in setting them. am. Use File::chdir facilities for localized operations.
	Functions Legend: Exported by default, exported on request, Win32 specific			
Modules	1 51115115115	in32 specific		Extra Information
Modules  Cwd	1 51115115115	in32 specific		<pre>Extra Information  use Cwd; my \$curdir = getcwd; print "cwd is \$curdir\n";</pre>

Cwd  File::Basename  File::Spec	Legend: Exported by default, exported on request, Wi  getcwd, cwd, fastcwd, fastgetcwd, getdcwd  abs path, realpath, fast abs path  fileparse, basename, dirname,  functional interface to methods: canonpath, catdir, getdir,	catfile, curdir, roc e imported by usin File::Find::name is used to icit argument to	use File::Find; find(sub {printf("- %-10s) if (-d or)	<pre>use Cwd; my \$curdir = getcwd; print "cwd is \$curdir\n";</pre>

### Topic: List Operations 🚧

List Operators					
Sorting lists	sort	Sort a list	<pre>my @sorted = sort @unsorted_list;</pre>	in place: my @data = sort @data;	
	reverse	Sort a list in reverse order	<pre>my @rsorted = reverse @unsorted_list;</pre>	in place: my @data = <u>reverse</u> @data;	
Filtering list with grep	my @adult_ages = grep \$_ > 18, @ages;		my @lucky_ages = grep /7\$/, @ages; # all that end with 7	my @read_ages = <u>grep</u> { \$_ >= 7 && \$_ <= 77 } @ages;	
Counting matches	my \$count	= <b>grep</b> \$_ > 18, @ages;			
	An expression, subroutine or block with trailing boolean can be used as the grep criteria. Each item in the list is identified inside grep by \$				
Transform a list with map					

			Topic: Process control			
Process Control	In Books: <u>LPo</u>	Important se	Important security information: peridoc perisec			
<b>Environment Variables</b>	Inside the <u>%ENV</u> hash.	Perl <a href="McConfig">McConfig</a> hash: Perl configuration information. For example, whether it support threads, what are path separators, etc  • To use it: use Config;				
Built-in Functions	Example	Description/ Notes				
<ul><li>system (2 functions)</li><li>using the shell</li><li>security risk?</li></ul>	<pre>system 'ls -1 \$HOME';</pre>	Run child process asynchronously using parent's stdin, stdout and stderr, using the OS native command shell.				
	<pre>system "cd \$project;</pre>	make &";	Use the Unix shell to execute a long running build asynchronously. However: avoid using the shell like this.  • Using the shell to build commands from unvalidated user input data may lead to security issues.			
<ul> <li>avoiding the shell</li> </ul>	system 'tar', 'cvf', \$tarfile, @	directories;	No shell invoked when more than 1 argument is passed to system. No shell interpretation, piping, re-direction done.			
<ul> <li>other syntax</li> </ul>	system( 'tar', @arguments);		O means success: unless (system 'tar', arguments) { print "tar command success\n"; }			
	<u>system(</u> { \$prog }, \$arg0, @a	args);				
	Note that if the string contain <b>no</b> shell metacharacters it is executed directly (not through a shell).					
<ul> <li>system return value:</li> <li>A value of 0 usually means all was OK.</li> </ul>	2 bytes: MSByte: child pro	gram exit code.				
	LSByte: system-spinformation bits:  • 0x80: set on co • 0x7f: signal nu	ore dump.	<pre>my \$childp_exitcode = \$retval &gt;&gt; 8; my \$had_core_dump = (\$retval &amp; 0x80) = my signal_number = \$retval &amp; 0x7f;</pre>	<ul> <li>         ← shift most significant byte     </li> <li>         ← use least significant byte     </li> </ul>		
exec	Unlike system, exec does not return to the parent Perl process. Use: exec 'the_program' or die "Could not run: \$!"; #or warn or exit					
backquotes``	Use backquotes to <b>capture the stdout</b> of a program. That's the main point of using it.  • The trailing newline is not filtered out; it can be filter by <b>chomp</b> .  • Chomp( my \$current_date = `date` );					
	<ul> <li>The value inside the backquotes is treated like the single double quote string argument of system: it will invoke the shell if there are any shell meta-characters and supports interpolation.</li> <li>The following example builds a dictionary (hash) of topics with the text extracted from peridoc.</li> <li>Note that `` is also written as qx/ /</li> <li>backquote operation in scalar context returns 1 string. In list context it returns a list of strings (1 per line).</li> </ul>					
Modules						
Capture streams	Capture::Tiny	Can be used to	capture the stdout and stderr streams for various ways if exe	ecuting other programs		
Inter-process support	IPC::System::Simple	Can also be used to capture streams and provide more inter-process support.  • It provides <a href="mailto:system">system</a> ; which never uses the shell, along with other useful functions.				
Processes as filehandles	In Books: LPo					
Perl ← program	Launching a process that pipes into the Perl process	open DATE, 'da	te   or die "Cannot pipe from date: \$!";	Use a bare word to define the DATE file handle.		
	pipes into the Peri process	open my \$date_	fh, '- ', 'date' or die "Cannot pipe from date: \$!";	This one and the others define a local file handle variable. The file handle variable can later be used to read, as the above one, but is not global.		
		open my \$ps_fh	n, '- ', 'ps', 'aux' or die "Cannot pipe from ps: \$!";			
		open my \$find_f	fh, '- ', 'find', qw(name '*.p[lm]' -print ) or die "Cannot pipe	from find: \$!";		
Perl ➡ program	Launching a process that the Perl process pipes into.	open my \$dispather_fh, ' -', 'dispatcher', qw ( '-to-perl-groups' 'Help!' ) or die "Cannot pipe to the dispatcher: \$!";				
Forking	In Books: LPo . See also: Linux fork(2) system call, QA: Why do we need fort to create new processes? Why fork woks the way it does?					
fork with exec and waitpid  See also: Other IPC functions Perl IPC	<ul> <li>fork the process into parent and child.</li> <li>in the child process start the program with exec</li> <li>In the parent process wait for the program termination with waited</li> <li>muless (\$process_id) {</li> <li># Inside the child process (created by fork)</li> <li>exec 'long_running_process' or die "Failed starting long_running_process: \$!";</li> <li># Inside the parent process, wait for completion of long_running_process.</li> </ul>					
with waitpid waitpid (\$process_id, 0);						

<u>Signals</u>	In Books: LPo				
<u>kill</u>	Sends a signal to a list of processes.  The signal may be identified by number or name (string), which is more portable.  The <pre>%Config{sign_name}</pre> provides the supported signal names.	kill 'INT', \$pid or die "Can't signal \$pid with SIGINT: \$!";			
	Note that the fat comma operator (=>) can be used to automatically quote signal name:	kill INT => \$pid or die "Can't signal \$pid with SIGINT: \$!";			
	If the signal is 0 or "ZERO" no signal is sent to the process; instead Perl checks if it's possible to send a signal to the process: ie: if the process exists.	unless (kill 0, \$process_id) {   warn "Process \$process_id is no longer running!"; }			
	If the signal is a negative number or a string that starts with '-' the signal is sent to the process group identified by the process scalar argument.	• <u>kill</u> '-KILL', \$process_group • <u>kill</u> -9, \$process_group			
Signal handlers	Set the signal handler by setting %SIG for the signal name (with no 'SIG' prefix) to a string holding the name of the subroutine.	<pre>\$<u>sig</u>{'INT'} = 'dispatcher_int_handler';</pre>			

# PerlTidy formatting control

perItidy option	Option	Impact
indentation style	<ul><li>-bl,</li><li>opening-brace-on-new-line</li><li>brace-left</li></ul>	<ul> <li>Without this option (the default) the code indentation style selected is <u>K&amp;R style</u>.</li> <li>With this option, the indentation style is <u>Allman/BSD style</u>.</li> </ul>
