Perl 5 Operators
                              Perl operators, listed below with their precedence and associativity.
Perl 5 Operators
                                                                                                                                               C Operators missing from Perl: unary &, unary * and (type)
                   Note:
                              · Quote and Quote-like operators: in Perl quotes are operators and they provide various kind of interpolating and pattern matching capabilities
Associativity: one of:
                              left
                                           terms and list operators (leftward)
                                                                                       ( )
                                                                                                                                          Note: print, sort, reverse, chmod, are list operators
  right
                              left.
                                           Arrow Operator:
  left
                              NA
                                           Auto-increment and Auto-decrement: ++ --
• NA : not associative:
                              right
                                           Exponentiation:
  cannot use more than one of these operators
                              right
                                           Symbolic Unary Operators:
                                                                                             -. \ and unary + and -
                                                                                                                                           Note: The operator \ <u>creates a reference</u>. See <u>example</u>.
                              left
                                           Binding operators:
   in sequence.
                              left
                                                                                              용
                                           Multiplicative Operators:
                                                                                         /

    CH: chained

                              left.
                                           Additive Operators:
                              left
                                           Shift Operators:
                                                                                      <<
                                                                                             >>
                              NA
                                           named unary operators
To get this information.
                              NA
                                           Class instance Operator:
                                                                                      isa

                                                                                  but in list context it returns a 9-tuple with date elements.
                                                                                                                                                         Mon Nov 30 09:06:13 2009
specific effect.

    Negation of a true value by "!" or "not"

                                                                                                            These scalar values are false:
Truth and falsehood
                              False in a boolean context:
                                                                                                                                                        All other scalar values are true, such as:
                                                                                                                                                          1 and any non-0 number
'' the string with a space in it
                                                                 returns a special false value.
                                                                                                             · undef - the undefined value
                                • the number 0,
1 The strings '0' and ''
                                   the strings '0' and ''.
                                                                                                            • 0 the number 0, even if you write it
                                                                 When evaluated as a string it is
mean false. The output of
                                                                 treated as ", but as a number, it is treated as 0.
                                                                                                               as 000 or 0.0
                                                                                                                                                        • '00' two or more 0 characters in a string
                                   the empty list ().
glob() may return a file
                                                                                                                the empty string.
                                                                                                                                                          "0\n" a 0 followed by a newline
                                   "undef
named '0'!
                                                                                                            • '0', a single 0 in the string.
                                                                                                                                                        • 'true'. 'false' . Even 'false' evaluates to true.
1 The bareword false

    All other values are true.

                                                                                                                                                 use constant { true => 1, false => 0 };
has a truth value of true!
                                One way to define valid true and false constant symbols that can be used in assignments (but see ):
                                                                                                                                                 if (-e $fname && -f _ && -r
                             File tests can be stacked (-r -w -e $fname) or combined as in the following example or:
File test operators
                                                                                                                                                  print("$fname exists, is readable\n"); }
See filetest -X
                                Notice the underscore in the example: it's the virtual filehandle _ accessing the last stat or Istat result :
                                           is readable by effective uid/gid
                                                                                                                                                        is a block special file.

                                                                                                                                    $days[0][2]
Archaic use of single
                                     ${days}
                                                              Same as $days, use before alphanumumerics.
                                                                                                                                    $d{99}{'Feb
                                                                                                                                                             Multi-dimensional hash
auote:
               $Dog'days
                                    $Dog::days
                                                              The $days variable inside the Dog package.
                                                                                                                                    $d{99, 'Feb'}
                                                                                                                                                             Multi-dimensional hash emulation

    Arrays are initialized by literal lists

                                                                                                   • You can assign a list of values to a list of variables. Useful to swap: ($val1, $val2) = ($val2, $val1);
list and Array
   0-based indexed (first
                                                                                                   • If there are more variables than values: the extra variables are set to <u>undef</u>. Extra values are ignored.
                                    · Lists are always flattened in Perl:
   index is 0).
                                       • This means that (1, 2, (10, 20, (100, 200), 30, 40), 4) is exactly the same is (1, 2, 10, 20, 100, 200, 30, 40, 4). Use references to create nested data structures.
   @name is $#name
                                                                                                                                   • A list is an ordered collection of scalars (of any type).
                                                          Array containing ($days[0], $days[1], ... #days[$#days])
                                    @days[3,4,5] Array <u>slices</u> containing ($days[3], $days[4], $days[5])
@days[3..5] Array <u>slices</u> containing ($days[3], $days[4], $days[5])
                                                                                                                                      An array is a variable that contains a list
                                                                                                                                     Reading beyond the end of array returns undef
                                    • Negative indices used in read access from the end: -1 is last item
                                        Use these negative indices to access from the end. Do not compute index with $#name -3, if the list size is 2, this will give invalid results.
                                                                                                                                    my @extracted = (6, 2, 8, 4);
                                                                                                                                                                                        my @digits = (0..9);

    array slices LPo

                                       Use a slice to select multiple elements from a list, array, or hash.
                                                                                                                                                                                        my @one2five = @digits[1..5]:
                                      Don't use a slice when you know you need exactly one element. An Ivalue slice imposes list context on the righthand side.
                                                                                                                                   my @choices = @digits[@extracted]
my $mod_time = (state $filename)[9];
     Simple explanation
                                                                                                                                                                                        my @premiers = @digit[1, 2, 3, 5, 7];

    Assign to array slice to update several values. ➡

                                                                                                                                    @extracted[1, 3] = (7, 9);

    Anonymous array := a type of array reference. Use it to build nested data structures.
    Array reference allows Perl to treat the array as a single item.

                                       What are the advantages of anonymous array? @ StackOverflow

    Anonymous arrays

                                       Perlref @ Perldoc, Perl reference tutorial @ Perldoc
                                                                                                                                                                                Initialize a hash slice with array context:
Hash/associative array
                                                                             Associative array (hash): keys-value pairs. Can be initialized as:
                                                    %days
 Hashes @ Perl Maven
                                                                                my %days = (Jan' => 31, Feb => $leap? 29 : 28, ...)
my %days = ("Jan", 31, 'Feb', $leap? 29 : 28, ...
                                                                                                                                                                                @char_to_num{'A' .. 'Z'} = 1 .. 26;
my %rating = (ron => 20, al => 50, steve => 80);
Note: keys are always
                   strings
                                                                                  Multiple values of a hash can be changed with the following construct:
                                                                                                                                                                                 # use fat comma to quote word left of it. 9
hash slice LPo
                                                                                                                                                                                my @names = ('ron', 'al');
                                                    @days{'J',F'} Hash slice returning a list containing ($days{'J'}, $days{'F'})
                                                                                                                                                                                @rating{ @names } = (25, 35); # update ron & al's ratings
key-value slices LPor ⇒

Format
Typeglob
                                    A typeglob is a symbol table structure with the slots of that symbol for the scalar, array, hash, code, format and I/O form of the symbol in the namespace.
                                                                            See: Object Oriented Perl, section 2.2.4. Typeglobs. Advanced Perl Programming, 1st Edition Section 3.2
                                    A reference is a scalar variable whose value is a pointer to another Perl variable. Use it to build more complex data types. Make reference with 1.
References
 Perl references intro
                                    The ref built-in returns a string describing the referent: ARRAY, HASH, CODE, FORMAT or IO. It will also return the class name of an object.
Perl reference tutorial
                                    my @array = qw(a, b, c);
print array[1]. # b
                                                                                                                                                                                        my $hash_ref = {a=>1, b=>2, c=>3};
                                                                             my \$array\_ref = ['a', 'b', "c\n"];
                                                                                                                                    my %hash = (a=>1, b=>2, c=>3);
Reference purpose
                                                                                                                                                                                        print ${$hash_ref}{c}; #3

                                                                             my $fct_ref = \&the_function;
                                                                                                                                                                                • &{ $the_function } (arg1, arg2);
                                                                                                                                                                                • $the_function->(arg1, arg2);
                                                                                                                                    with the simpler arrow notation:
                                                                                                                                    my p = sub \{ my v1 = shift; my v2 = shift; return v1 ** v2; \};
                                    Using an anonymous subroutine, always calling it indirectly:
                                                                                                                                    say $op->(10, 4); # prints 10000
                                    Unlike most programming languages Perl automatically creates missing
                                                                                                                                    · Checking if a nested data stru
                                                                                                                                                                                                                   It's also possible to lexically
Autovivification. 👍
                                    parts of arrays, hashes when an undefined value is referenced.
                                                                                                                                                  it will always exist!! See BUG section here.
                                                                                                                                                                                                                   disable it, with the pragma:
What is autovivification?
                                    Also see: autovivification in for loop but not assignment?

    Prevent that by checking each level data in step.

                                                                                                                                                                                                                      no autovivification;
Perl surprise/problem with
autovifification
                                                                                                                                   no autovivification 'exists'; # turn it off just for exists checks. See others.
                                    no autovivification; # turn off vivification except for setting value
                                    A closure binds its environment and keeps it to use it when invoked.
Closures
                                                                                                                                    sub make greeting
                                                                                                                                          make_greeting {
my $greet = shift;
my $greet_fct = sub {
   my $name = shift;
   print "$greet, $name!\n";
   Perl closure
                                      In the example at right, a greeter function is built and returned,
                                       remembering how to greet. It is used like this:
                                         my $fr = make_greeting("Bonjour");
my $it = make_greeting("Buongiorno")
   Note how easy it is to
create a closure in Perl: a
                                         $fr->('Brigitte'); # prints: "Bonjour, Brigitte\n" 
$it->('Madonna'); # prints: "Buongiorno, Madonnal\n"
simple block that defines
                                                                                                                                          return $greet fct; # return ref to internal function
a lexical variable
referenced by subroutines defined in that block. The
                                                                                                                                    { my $count;  # lexically scoped variables are only accessible inside the block sub add_1 { count += 1; } # but the subroutine is not lexical it's visible
                                    A code block defining lexical variable(s) and subroutines consist of a closure too! With the following example, the add_1() subroutine
variable is not accessible outside of the block but
```

increments the \$count and that's returned by get_count(). The

Scount variable cannot be accessed from anywhere else!

the subroutines are!

return count; } # in the package (main by default).

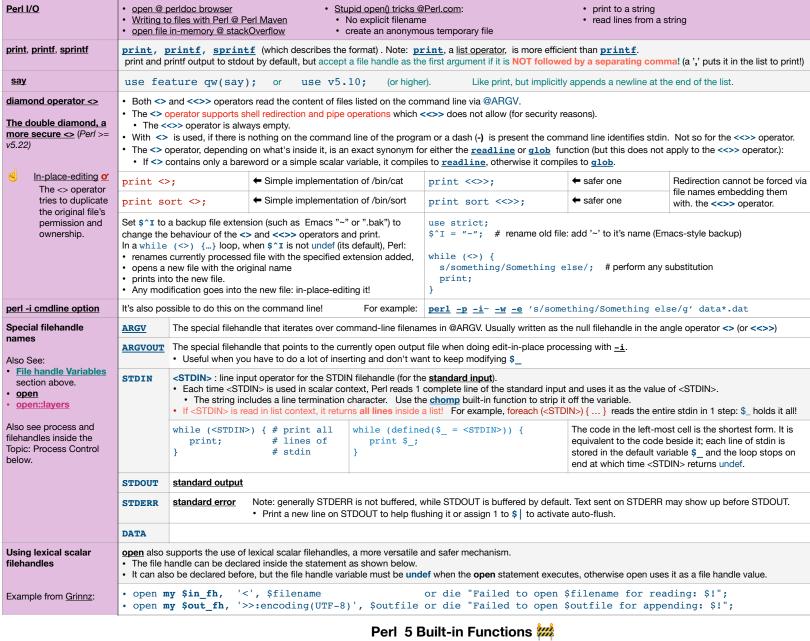

The lifetime of the subroutines is the program, keeping the referred-to variables alive!

Scalar values	Numeric		literals examp	oles: Note: leading 0 w	ork only for lite	erals, not for string-to	-number conversions.	Useful related <u>builtin functions</u>
numeric: Note: underline separators can be used inside decimal, hexadecimal and binary literals.	bigint - transparent big integer support. bignum - transparent big number support. floating-point: using the system's native format. bigrat - transparent big rational number support. A variable holding an integer can be converted to floating-point if the operation done to it requires it (such as dividing 1 by 2).		my \$x = 1234 my \$x = 6.02 my \$x = 0x1f port. my \$x = 4_29 my \$x = 0x12 my \$x = 0377 my \$x = 0377 my \$x = 0011	my \$x = 12345; # integer my \$x = 12345.67; # floating point my \$x = 6.02e23; # scientific not my \$x = 0x1f.0p3; # power² exponen my \$x = 4_294_967_296; # underline for my \$x = 0x1234_5678; # underline in it my \$x = 0377; # octal my \$x = 00377; # octal also my \$x = 0b1100_0010; # binary with un my \$x = 0xff55; # hexadecimal		rtation nt: Perl >= v5.22 legibility hex is also OK Perl >= v5.34	oct - for: binary, octal, hex hex POSIX::ceil POSIX::floor abs	
• string	 double-quoted strings: perform backslash and variable interpolation of expression that begin with \$ (a scalar) or @ (an array). Hashes cannot be interpolated. single-quote strings: only perform \' and \\ substitution (to ' and \ respectively), nothing else. Single quote and double quote strings can spread multiple lines: it embeds the newline character on each new line. \n is only expanded in double quoted strings. In single quote string it is treated as two characters; no substitution is done (as explained above). 						·	
Unicode support	Use Unicod	de literally in a progr	am; add the <u>utf8 p</u>	ragma: use utf8;	See: Perl Un	icode Tutorial, Perl U	nicode Introduction, Perl	Unicode Support @ perldoc

Auto-flush control order of output @ Perl Maven Suffering from Buffering?	HANDLE->autoflush(EX SOUTPUT_AUTOFLUSH \$I		Perl activates file buffering by default. Assign 1 to \$ to activate auto-flush.	Last read file handle	\${^LAST_FH}			

Perl 5 Input/Output

Example from Grinnz:	• open my \$in_fh, '<', \$filename or die "Failed to open \$filename for reading: \$!"; • open my \$out_fh, '>>:encoding(UTF-8)', \$outfile or die "Failed to open \$outfile for appending: \$!";						
	Perl 5 Built-in Functions 🚧						
Perl Functions Perl syntax	To get information about a Perl function from the command line use the perldoc -f command. • To get information about print use: perldoc -f print						
!Cautionary notes	Some of the Perl functions exhibit various limitations and the vary over Perl versions. This section describes the ones I am aware and the proposed alternatives.						
each keyword is broken Use Var::Pairs instead.	Do NOT use the built-in each. It is broken, as described by <u>Damian Conway</u> in his <u>Modern Perl Best Practice O'Reilly course</u> , section control structure. • each is not re-entrant: • nested loops of each over the same hash does not work as expected and will create infinite loop since the nested loop each juts iterates from where the first loop each left it. • Exiting the loop leaves the state of the each internal pointer at the current location. • If you use each on the same hash later it will resume from where it left, it will not start form the beginning.						

Perl 5 Statements

				141011101110	
Loop control	See <u>perlsyn</u> for more informati	ion on Perl syntax	which includes declaration	ons, blocks, loops, labels, subrouting	nes, etc
Use the <u>last</u> and <u>redo</u> inside a naked block of code to control looping.	loop control keywords: work in the folk			on) { } on) { } n; continue) { } . }	Notes: • The while and foreach loops may have a continue block: executed before evaluating condition again, which corresponds to the 3rd part of a for loop statement. See this @ stackOverflow. • Blocks can be labelled of as targets to last, next, and redo
Statement modifiers	if EXPR unless EXPR while EXPR until EXPR for LIST foreach LIST when EXPR	processed. There has "_END_" o		a list context; the complete list is wing trying to stop on a line that reads all of STDIN:	The while statement imposes a scalar context; it takes one line at a time from <stdin> and the following code works properly: while (<stdin>) { last if /_END/; ; }</stdin></stdin>
do block	The do block is *very useful* to set a value based on several conditions, just as the ?: conditional operator but with an explicit block that may use scoped variables. Takes advantage of a block value is the value of the last expression executed inside the block. Do *not* return from the block. The last, next and redo cannot be used inside do blocks.			<pre>if (\$perl_nirvana < 5 & elsif (some_other_cond elsif (\$emacs_nirvana</pre>	<pre>ccs_nirvana) = check-nirvana-levels(); & \$emacs_nirvana < 8) { 'study-Perl' } d()) { 'time-to-cook' } < 7) { 'look-into-eieio' } go-skiing' : 'go-canoeing' }</pre>
Compound statements					
if, elsif, else					
unless					
?: conditional operator					

Perl 5 Subroutines

			1 1							
Perl subroutines	See Object Oriented Perl, section 2.1.4 : Subroutines									
Defining subroutine	Defined with the <u>sub</u> keyword followed by a block.		<pre>sub greet { print "hello!\n"; }</pre>							
Calling a subroutine	If the subroutine definition follows its invocation, passubroutine name are required, as in: greet();	arentheses after the	 But if the definition was above the call, the parentheses are optional; as in: greet; Subroutine sigil is &. It can optionally be used in a call; as in &greet or &greet(); 							
pass current @_array	Call with & prefix without args, as in ⊂_function	to pass current @	array. Used to call a helper subroutine with in the primary of	one, providing all its arguments.						
• goto	From a subroutine use goto ⊂_function; to trans	From a subroutine use goto ⊂_function; to transfer control to that subroutine instead of calling it. It also passes the current @_ array to it.								
calling a method	Parentheses are required if arguments are passed to optional if there is no arguments.	o method, but	<pre>\$obj->method_with_args(\$val1, \$valb); \$obj->method_without_arg; \$obj-></pre>	>method_without_args();						
subroutine &	Why we teach the subroutine ampersand Why should I use the & to call a Perl subroutine? @	StackOverflow	Another point of view: <u>Subroutines and Ampersands</u> Note it must be used to <u>make a reference</u> to a subroutin	e: \$greeter = \& greet;						
subroutine arguments passed by list always variable by nature	The arguments passed to a subroutine are available special a rray. The caller code supplies a list of values. Remember nested lists lists are flattened in Perl.		@sorted = alpha_order('Nice', 'Québec', 'Montréal'); @sorted = number_order @unsorted_numbers; @sorted = alpha_order('Trois-Rivières', @sorted, 'Gaspé', 'Rimouski');							
named arguments Note: The @_ is an alias to the passed values; changing them inside the subroutine affects the caller's values.	Since hash declaration take a list of key/value pairs implement a passing named arguments! It's also possible for the subroutine to set defaults expected arguments by taking advantage of the fallists, list are flattened and hash can be assigned a values are used.	for some of the ct that hash are	<pre>Implementation:</pre>							
Subroutine Prototypes	An older Perl feature. Clashes with subroutine signatu	ires as of Perl v5.20.	In $Perl >= v5.20$ put the :prototype attribute before sub	routine prototype parenthesis.						
Subroutine signatures	Exactly zero arguments ()		Zero or 1 argument, no default, unnamed:	(\$=)						
Perl >=5.36: StablePerl >= 5.20:	Zero or 1 argument, no default, named (\$\square\$	val=)	Zero or 1 argument, named, with default	(\$val=1)						
Experimental See: Use v5.20	exactly 1 named argument: (\$1	val)	Exactly 2 arguments	(\$v1, \$v2)						
subroutine signatures	2, 3 or 4 arguments no defaults: (\$v1,	\$v2, \$=, \$=)	2,3 or 4 arguments, 1 default:	(\$v1, \$v2, \$v3='a', \$=)						
	Two or more, any number of arguments. (\$1	1, \$v2, @)	Two or more arguments, remainders into a named array:	(\$v1, \$v2, @rest)						
	Two or more arguments: an even number (\$1	1, \$v2, %)	Two or more arguments, remainders into a named hash:	(\$v1, \$v2, %rest)						
	Class method (\$c	class,)	Object method	(\$self,)						
Returned value. Detecting calling context with wantarray	 The result of the last evaluated expression is implicitly returned. The return operator can be used but it's not required unless used to change execution flow (return immediately from the subroutine). The subroutine can return a scalar in scalar context or a list if called in list context. Inside the subroutine, use the wantarray function to determine the calling context of the subroutine call and why it should return: 									
Identify caller	The caller built-in returns information about the subro	outine caller inside ar	n array: (package, file_name, file_line). In scalar context it re	turns the package only.						
Continuation with goto	The goto built-in can be used by a subroutine to conf	inue its execution in	to another subroutine. Not for all but useful in some specific	c cases such as autoloading.						

Perl 5 Classes, Objects and Methods

Perl Classes	

Perl 5 Modules

Perl Modules									
Perl core modules	How to detect where a module is installed : perldoc -1 Module How to check if a module is part of Perl core : corelist Module (Perl >= v5.9.2)								
Access to Modules	Provide access to modules in your code with one of the following: do , require or use								
Modules @perltutorial Modules Using simple modules ©	 Looks for the module file by searching the @INC path. Performed at run time (and therefore can be done conditionally). If Perl finds the file, it places the code inside the calling program and executes it. Otherwise, Perl will skip the do statement silently. The "included" code does not have access to the lexical variables from the main program. Skip the @INC path lookup if given a file path starting with ./,/, or / 								
	Loads the module file once, also searching the MIC path . Performed at run time (and therefore can be done conditionally). • If the require for the same file appears twice, Perl ignores it. Perl will issue an error message if it cannot find the file (as opposed to Months: It to appear to appear twice, Perl ignores it. Perl will issue an error message if it cannot find the file (as opposed to <a "\n";'<="" @inc),="" \n",="" href="Months: It to appear to appe</td></tr><tr><th>The normal way to access Perl modules ➡</th><th>Similar to require except that Perl applies it before the program starts: it's done at compile time. Modify it dynamically in a BEGIN block. See IntPo. • Therefore the use statement cannot be invoked inside conditional statements such as if-else. Used often to include a module in a program. That imports the defaults as defined by the module's code. Select what to import with one of the two equivalent forms: (See IntPo): • use Module::Name ('function_a', 'function_b'); • use Module::Name (); # import nothing. All accesses to the module must be done with Module::Name::something</th></tr><tr><th>Error handling for:</th><th>For the above statements to work Perl must be able to identify the location of the requested module(s).</th></tr><tr><th>Can't locate in @INC How to fix that</th><th>• Perl looks for a module code inside the directories identified by the <u>@INC</u> array. If you have. <u>use</u> The::Module; inside your code, Perl looks for a sub-directory named 'The' containing a file named 'Module.pm' inside each <u>@INC</u> directory. If Perl does not find it, there are multiple ways to solve the problem:</th></tr><tr><th>See Also: IntPo</th><th> Add the required directory to the list of directories identified in the ':' separated list in the PERL5LIB environment variable. (use ';' as separators in Windows). Add a use <u>lib</u> 'path/to/the/directory'; statement inside your Perl file to add the required directory when executing a specific piece of Perl code, at compile time. </th></tr><tr><th>See: show-perl-inc @ USRHOME</th><th colspan=8> Run Perl with the -I (capital i) option to run the code with the extra directory added to @INC array. To List the directories used by Perl from one of the following equivalent command lines: perl -e 'print join(" li=""> perl -le 'print for INC';' You can also get more information with perl -V 								
Specially Named Blocks	5 specially named blocks are run at the beginning or end of a running program: BEGIN, UNITCHECK, CHECK, INIT and END. See: BEGIN block - running code during compilation. Note the security risk warnings. The BEGIN block is used to implement other Perl functionality.								

In Perl a package can span several files and one file may contain the code of several packages.

The package starts with the package literal contains the name of the current package.

Declare packages

Topic: Data Introspection

Data Introspection								
Using Perl Debugger	Debug a pr	rogram:	perl -d program	perl -d program_name program_args				
Debugger Tutorial	Debug inte	ractive session:	perl -d -e 0					
Debugger commands	q	Quit debugger		s	single step			
	h	help. List all availa	able commands.	x	evaluate expression			
Modules for Data introspection				• Pas	s similar to the x command of the debugger. ss reference to the variables , otherwise it extends the and show each entry as its own variable.	<pre>• print Dumper(\@array); • print Dumper \%hash;</pre>		
	Data::Dump (Requires Perl >= v5.6.0)			comp	des a dump function that has nicer output, but is not gatible. mp() prints on the stdout. No need to use print.	use Data::Dump qw(dump); dump(\@array); dump(\%hash);		
	Data::Printer		to t	rovides the p subroutine that does not require a refere the variable as it inspects it first. prints on the stdout. No need to use print.	use Data::Printer; p(@array); p(%hash);			
Data Marshalling Data Serialization		everal modules, eit links at left for more		re or o	utside, that provides mechanism to marshall/serialize a	and unmarshall/de-serialize data.		

Topic: Directory Operations

Directory Operations	In Books: LPo				
Opening Files	All file open operations are relative to the <u>current workin</u> relative file names)	ng directory (for	open my \$filehandle, '<:utf8', 'a_relative/path.txt'		
Creating temporary files	File::Temp (Perl >= v5.6.1). <u>Using File::Temp</u> • Also see <u>IO::File</u>				
Built-in Functions	Related Functions/Packages / Descriptions			Notes	
Getting file names by: Globbing: with glob	File::Glob (Perl >= v5.6.0) - provides more control.	Example:	<pre>my @all_files = glob ' my @perl_files = glob '</pre>	*'; *.pm *.pl'; # 2 globs, space-separated	
with the glob operator <>	The <> operator is identifying: • a filehandle, when: the item inside <> is a Perl identifier or an indirect file handle read scalar, • a glob expression otherwise.	Glob examples:	my @perl_files = <'*.pm	# 1 glob: no space, no need for string n *.pl'>; # 2 globs, space-separated	
			<pre>my \$etc_dir = '/etc'; my @etc_dir_files = <\$e</pre>	etc_dir/* \$etc_dir/.*>;	
			my @files = <larry *="">;</larry>	# a glob	
	See: readline	Filehandle	my @his_lines = <larry></larry>	; # a filehandle read	
		examples:		; # indirect filehandle read of LARRY handle ine LARRY; # another way to write above ine \$name;	
with a directory handle LPo	opendir: open a directory: get a directory handle readdir: read the directory handle. But see this. closedir: close the directory handle. DirHandle (Perl <= 5.5) File::Spec::Functions (Perl >= v5.5.4) Path::Class	Example: iterate explicitly over a list of file names extracted from the directory using these 3 functions.	foreach \$file (readdir	r die "Failed opening \$dir: \$!"; \$dh) { inside \$dir\n"; # A no path in name!	
Creating directory	• mkdir	Example:		permissions); # octal for permissions # do not use "0700", it's 700 decimal!	
Removing directory	rmdir Removes an empty directory. File::Path remove tree , rmtree remove dir & files (Files Files Files	Perl >= v5.0.1)			
Removing files	• unlink a list or \$_		<pre>unlink 'file1.txt', 'file2.txt'; unlink qw(file1.txt file2.txt); unlink glob 'file?.txt'</pre>		
Renaming files	rename an old file name to a new one. The fat comma operator is sometimes used to highlight what is the old and the new name.	As in here:	<pre>rename 'old_name' , 'new_name'; rename old_name => 'new_name'; # use fat comma to quote word left of it.</pre>		
Changing permissions	chmod changes file permissions				
Changing ownership	chown changes file ownership				
Creating Hard link	link to create a hard link				
Creating symbolic link	symlink to create a symbolic link				
chdir Change current working directory	File::chdir File::HomeDir	• chdir without \$ENV{LOGDIR	environment values if they are	er home directory using the \$ENV{HOME} and e set. The File::HomeDir module helps in setting them. m. Use File::chdir facilities for localized operations.	
Modules	Functions Legend: Exported by default, exported on request, W.	in32 specific		Extra Information	
Cwd	getcwd, cwd, fastcwd, fastgetcwd, getdcwd abs path, realpath, fast abs path			<pre>use Cwd; my \$curdir = getcwd; print "cwd is \$curdir\n";</pre>	
File::Basename	fileparse, basename, dirname,				
File::Spec File::Spec::Functions	functional interface to methods: canonpath, catdir, splitpath, splitdir, catpath, abs2rel, rel2abs. All can be			ne is absolute, path. devnul, tmpdir, case tolerant,	
File::Find : Traverse a directory tree. See: File::Find::Closures	find, finddepth, %options. In wanted: File::Find::dir, Note that \$_gets the base name of the file (no path). It perform filetest operations in the example here (as expl -s, and implicit argument to -d and -f). This traverses the	:: %4d, %s\n", \$_, -s \$_, File::Find::name) -f) and (\$_ ne "."); }, '.'); If files inside all directories not showing the directory name			

Topic: List Operations

List Operators					
Sorting lists	sort	Sort a list	<pre>my @sorted = sort @unsorted_list;</pre>	in place: my @data = sort @data;	
	reverse	Sort a list in reverse order	<pre>my @rsorted = reverse @unsorted_list;</pre>	in place: my @data = reverse @data;	
Filtering list with grep	my @adult_ages = <u>grep</u> \$_ > 18, @ages;		my @lucky_ages = grep /7\$/, @ages; # all that end with 7	my @read_ages = <u>grep</u> { \$_ >= 7 && \$_ <= 77 } @ages;	
Counting matches	my \$count	= grep \$_ > 18, @ages;			
	An expression, subroutine or block with trailing boolean can be used as the grep criteria. Each item in the list is identified inside grep by \$				
Transform a list with map					

Topic: Process control

			iopic. Pi	rocess control			
Process Control	In Books: <u>LPo</u>	Important security information: peridoc perisec					
Environment Variables	Inside the <u>%ENV</u> hash.	Perl %Config hash: Perl configuration information. For example, whether it support threads, what are path separators, etc • To use it: use Config;					
Built-in Functions	Example	Description/ Notes					
system (2 functions)	<pre>system 'ls -1 \$HOME';</pre>	Run child process asynchronously using parent's stdin, stdout and stderr, using the OS native command shell.			out and stderr, using the OS native command shell.		
using the shell <u>security risk?</u>	<pre>system "cd \$project;</pre>	Use the Unix shell to execute a long running build asynchronously. Using the shell to build commands from unvalidated user input data may lea		•			
avoiding the shell	system 'tar', 'cvf', \$tarfile, @	Odirectories; No shell invoked when more than 1 argument is passed to		nore than 1 argument is passed to	system. No shell interpretation, piping, re-direction done.		
other syntax	system('tar', @arguments);	0 means success: unless (system 'tar', arguments) { print "tar command success\n"; }			ts) { print "tar command success\n"; }		
	system({ \$prog }, \$arg0, @a	args);					
	Note that if the string contain no shell metacharacters it is executed directly (not through a shell).						
• A value of 0 <i>usually</i> means all was OK.	2 bytes: MSByte: child pro	gram exit code.	<pre>my \$retval = system();</pre>				
	LSByte: system-sj information bits: • 0x80 : set on co • 0x7f : signal no	ore dump.	my \$childp_exitcode = \$retval >> 8;				
exec	Unlike system, exec does not	return to the pare	nt Perl process. Use:	<pre>exec 'the_program' or die</pre>	"Could not run: \$!"; #or warn or exit		
backquotes``	Use backquotes to capture the The trailing newline is not fill			nt of using it.	<pre>chomp(my \$current_date = `date`);</pre>		
	invoke the shell if there are a • The following example bu • Note that `` is also writter	any shell meta-cha uilds a dictionary (n as qx/ /	es is treated like the single double quote string argument of system : it will y shell meta-characters and supports interpolation. ds a dictionary (hash) of topics with the text extracted from peridoc. as qx/ / context returns 1 string. In list context it returns a list of strings (1 per line).		<pre>my @topics = qw(die warn exit); my %info; foreach (@topics) { \$info{\$_} = `perldoc -t -f \$_`; }</pre>		
Modules							
Capture streams	Capture::Tiny	Can be used to capture the stdout and stderr streams for various ways if executing other programs					
Inter-process support	IPC::System::Simple		ed to capture streams and provide more inter-process support. stemx which never uses the shell, along with other useful functions.				
Processes as filehandles	In Books: LPo						
Perl + program	Launching a process that pipes into the Perl process	open DATE, 'date or die "Cannot pipe from date: \$!";			Use a bare word to define the DATE file handle.		
	pipes into the ren process	open my \$date_fh, '- ', 'date' or die "Cannot pipe from date: \$!";			This one and the others define a local file handle variable. The file handle variable can later be used to read, as the		
		open my \$ps_fh, '- ', 'ps', 'aux' or die "Cannot pipe from ps: \$!"; above one, but is not global.			above one, but is not global.		
		open my \$find_fh, '- ', 'find', qw(name '*.p[lm]' -print) or die "Cannot pipe from find: \$!";					
Perl ➡ program	Launching a process that the Perl process pipes into. Cannot pipe to the dispatcher: \$!"; Perl process pipes into.						
Forking	In Books: LPo . See also: Linux fork(2) system call, QA: Why do we need fort to create new processes? Why fork woks the way it does?				/hy fork woks the way it does?		
fork with exec and waitpid See also: Other IPC functions Perl IPC	fork the process into parent and child. in the child process start the program with exec In the parent process wait for the program termination with waitpid	<pre>defined(my \$process_id = fork) or die "Fork failed: \$!"; unless (\$process_id) { # Inside the child process (created by fork) exec 'long_running_process' or die "Failed starting long_running_process: \$!"; } # Inside the parent process, wait for completion of long_running_process. waitpid(\$process_id, 0);</pre>					
Signals	In Books: <u>LPo</u>						
<u>kill</u>	Sends a signal to a list of proce • The signal may be identified • The <u>%Config{sign_name}</u>	by number or na	me (string), which is more portable. ported signal names.		kill 'INT', \$pid or die "Can't signal \$pid with SIGINT: \$!";		
	Note that the fat comma operation.	erator (=>) can be	used to automatically quote signal name:		kill INT => \$pid or die "Can't signal \$pid with SIGINT: \$!";		
	If the signal is 0 or "ZERO" r signal to the process: ie: if the signal to the process: ie: if the signal to the process ie: if the signal is 0 or "ZERO" representations in the signal is 0 or "ZER		the process; instead Perl checks if it's possible to send a		unless (kill 0, \$process_id) { warn "Process \$process_id is no longer running!"; }		
	If the signal is a negative nuidentified by the process sca		at starts with '-' the signal is sent to the process group		• <u>kill</u> '-KILL', \$process_group • <u>kill</u> -9, \$process_group		
Signal handlers	Set the signal handler by set 'SIG' prefix) to a string holdi		<pre>\$SIG{'INT'} = 'dispatcher_int_handler';</pre>				
Error Logging and Reporting	 Perl supports the warn buil-in to generate warnings on stderr. The <u>Carp::carp</u> from the <u>Carp</u> package, provides more information. • <u>Log::log4perl</u> is an implementation of the popular Apache <u>Log4j</u> for Perl.						

PerlTidy formatting control

perItidy option	Option	Impact
indentation style	-bl, opening-brace-on-new-line brace-left	 Without this option (the default) the code indentation style selected is <u>K&R style</u>. With this option, the indentation style is <u>Allman/BSD style</u>.
