Perl scripts

Writing Perl scripts	Impose strictures in Perl files t	Impose strictures in Perl files to prevent errors by adding one of the following use lines. Also see the strictures package.		
Use the following at the beginning of Perl script files. perldiag @ perldoc	<pre>#!/usr/bin/env perl use strict; use warnings; # for testing only:</pre>	#! /usr/bin/perl -w use v5.12; # loads strict use v5.35; # &loads warnings A use diagnostics produces more info but increases startup time.	Executable Perl script should have a valid shebang line identifying the appropriate location of the Perl interpreter. It may have to be modified at installation time (OpenGroup/SUS). It's best to: use warnings; perl -w generates warning for all Perl code in the program including modules used by the program. But most Perl code should also activate the strict Perl rules and warnings to detect warnings. See: Barewords in Perl	
	<pre>use diagnostics;</pre>	Alternative: perl -Mdiagnostics . Emacs p	el-perl-critic command can report diagnostic.	
use version/features	<u>use</u> v5.36;	This can be used to enable both the strict and warning pramas as well as several <u>named features</u> . • See the <u>table listing the feature bundles per Perl versions</u> .		

```
Perl 5 Operators
Perl 5 Operators
                              Perl has a large number of operators, listed below with their precedence and associativity.
                               C Operators missing from Perl: unary &, unary * and (type)

Quote and Quote-like operators: in Perl quotes are operators and they provide various kind of interpolating and pattern matching capabilities.
                    Note:
Associativity: one of:
                              left
                                           terms and list operators (leftward)
  right
                              left
                                           Arrow Operator:
                              NA
                                           Auto-increment and Auto-decrement:

    NA : not associative:

                              right
                                           Exponentiation:
  cannot use more than
                                           Symbolic Unary Operators:
                                                                                        ! - -. \ and unary + and -
                              right
                                                                                                                                             Note: The operator \ <u>creates a reference</u>. See <u>example</u>.
  one of these operators
                                                                                        =~ !~
                                           Binding operators:
   in sequence.
                              left
                                           Multiplicative Operators:
                                                                                        * / % x

    CH: chained

                              left
                                           Additive Operators:
                              left
                                           Shift Operators:
To get this information,
                              NA
                                           named unary operators
                              NA
                                           Class instance Operator:
                                                                                       isa
                              СН
                                                                                       as numbers: < >
                                                                                                                                  as strings: 1t
perldoc perlop
                                           Relational Operators:
                                                                                                                                                        gt
                                                                                                                                                                le
                              CH/NA
                                                                                       as numbers: == !=
                                           Equality Operators:
                                                                                                                                  as strings: eq
                                                                                                                                                                cmp
                              left.
                                           Bitwise And:
                                                                                           &.
                              left
                                           Bitwise Or and Exclusive Or:
                                                                                           |.
                              left
                                           C-style Logical And:
                              left
                                           Logical Defined-Or:
                                                                                       П
                                                                                                  11
                              NA
                                           Range Operators:
                              right
                                           Conditional Operator:
                              right
                                           Assignment Operators:
                                                                                                            /=
                                                                                                            ,
응=
                                                                                       goto last next redo dump
                              left
                                           Comma, fat-comma Operators:
                                                                                     , =>
                              NA
                                           list operators (rightward)
                                           Logical Not:
                              right
                                                                                     not
                              left
                                           Logical And:
                                                                                     and
                              left
                                           Logical or and Exclusive or:
                                                                                     or xor
                                           Converts a string that starts with digits into a number.
                                                                                                                                                           -+- is essentially - + - or - - but a + to allow placing
                              -+-
                                                                                                              print -+- '22les poulets!';
trick operators 🔔
                                                                                                              # prints 22
                                                                                                                                                          them together. The 0+ does the same as -+-, but
                              0+
                                                                                                                                                          the second has higher precedence.

                                                                                                                                                          $ perl -le 'print ~~localtime'
Mon Nov 30 09:06:13 2009
                                           Force scalar context.
                                                                                   In scalar context localtime() returns human readable time,
specific effect.
                                                                                   but in list context it returns a 9-tuple with date elements.
Truth and falsehood
                              • False in a boolean

    Negation of a true value by "!" or "not"

                                                                                                              So the following scalar values are
                                                                                                                                                           All other scalar values, including the following are
                                                                                                              considered false:

• undef - the undefined value

• 0 the number 0, even if you write it
                                                                   returns a special false value.
When evaluated as a string it is
                                context:
                                   the number 0,

    1 any non-0 number
    ' ' the string with a space in it
    '00' two or more 0 characters in a string
 1 Remember that the
                                • the strings '0' and '',
                                                                   treated as ", but as a number, it is treated as 0.
strings '0' and " mean false. The output of
                                                                                                                 as 000 or 0.0
                                • the empty list (),
                                                                                                              " the empty string.'0', a single 0 in the string.
                                                                                                                                                          • "0\n" a 0 followed by a newline
glob() may return a file named '0'!
                                    "undef

    All other values are true.

'false' . Even the string 'false' evaluates to true.

🛕 a bareword false has
                                                                                                                                                   use constant { true => 1, false => 0 };

    one way to define valid true and false constant symbols that can be used in assignments (but see ←):

File test operators
                                                                                                                                                    if (-e $fname && -f
                             It is possible to combine the file test operator with the AND operator as in the following example:
                                                                                                                                                                                  && -r
                                                                                                                                                     print("$fname exists, is readable\n"); }
                                     Notice the underscore in the example: it's the {\it virtual file} accessing the last {\it lstat} result :
The operators check if
                                           is readable by effective uid/gid
                                                                                                                                                          is a block special file.

Perl 5 Constants and Variables

Perl Constants Perl pragma to declare constants. A But be aware that these are still not read-only, that they inject sub-routines and have several limitations. Read the doc! CPAN modules for defining constants by Neil Bowers . Of particular interest: Const::Fast and Attribute::Constant for efficient read-only constants. **Perl Variables Name** All: underscore or letter of the first character. **Array Naming Conventions** Similar conventions, except that array names should be **plural**. • Module names are MixedCaseNoUnderscores • Constants are UPPERCASE_WITH_UNDERSCORES Case is significant in · Local variables: \$lowercase all names. ASCII by Global variables: \$Title Case default, UTF-8 if the utf8 @locals Package wide vars are Mixed_Case_With_Underscores \$UPPER_CASE Constants: @Global Arravs pragma is used. Functions/methods are lowercase with underscores · All variables: words separated by underscores. @CONSTANT_ARRAYS Avoid ALLUPPERCASE: used by Perl special variables Perl types Sigil \$foo Simple scalar value Scalar \$ \$days[28] 29th element of array @days \$days{'Feb'} Value associated with the Feb key of hash %days Same as \$days, but unambiguous before alphanumerics. Useful inside strings for interpolation of variables followed by other letters. \${davs} The \$days variable inside the Dog package. \$Dog::days \$Dog'days Same as above. However this is an archaic use of the single quote. \$#days \$days->[28] Last index of array @days. 29th element of array pointed to by reference \$days. \$days[0][2] Multi-dimensional array \$d{99}{'Feb'} \$d{99, 'Feb'} Multi-dimensional hash Multi-dimensional hash emulation list and Array Array containing (\$days[0], \$days[1], ... #days[\$#days]) . • A list is an ordered collection of scalars (of any type). @days Array slice containing (\$days[3], \$days[4], \$days[5]).

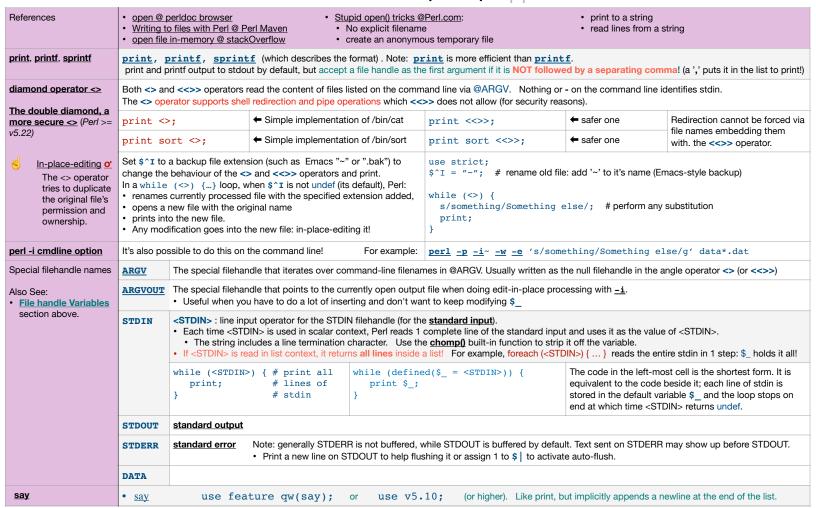

Array slice containing (\$days[3], \$days[4], \$days[5]). · 0-based indexed (first @days[3,4,5] An array is a variable that contains a list. index is 0). @days[3..5] · Reading beyond the end of array returns undef Last index of array • Negative indices used in read access from the end: -1 is last item. Use these negative indices to access from the end. Do not compute index with \$#name -3, if the list size is 2, this will give invalid results. Use a slice to select multiple elements from a list, array, or hash. · An Ivalue slice imposes list context on the righthand side. Don't use a slice when you know you need exactly one element. What are the advantages of anonymous array? @ StackOverflow
 Perlref @ Perldoc, Perl reference tutorial @ Perldoc Anonymous array := a type of array reference.
Array reference allows Perl to treat the array as a single item.
This can be used to build, nested data structures. Anonymous arrays %days Hash/associative array Associative array (hash): keys-value pairs. Can be initialized as: Initialize a hash slice with array context: %days = (Jan => 31, Feb => \$leap? 29 : 28, ...) %days = ("Jan", 31, 'Feb', \$leap? 29 : 28, ...) @char_to_num{'A' .. 'Z'} = 1 .. 26; @days{'J',F'} Hash slice containing (\$days{'J'}, \$days{'F'}). Subroutine & is needed to create reference to subroutine & &foo Typeglob *foo See: Advanced Perl Programming, 1st Edition Section 7 kinds of package scalar variables 4. subroutine name 6. file handles variables or variable-like elements in Perl: array variables hash variables 5. format names 7. directory handles how to format output in Perl?, Perl-Formats · See write and select Numeric literals examples Scalar values Useful related builtin functions Note: leading 0 work only for literals, not for string-to-number conversions. · integer: using the system's native format. my \$x = 12345;oct - supports binary, octal, # integer numeric: # floating point
scientific notation bigint - transparent big integer support. \$x = 12345.67;6.02e23; bignum - transparent big number support. \$x my <u>hex</u> floating-point: using the system's native format.
 bigrat - transparent big rational number support. POSIX::ceil \$x = 0x1f.0p3; power² exponent: Per1 >= v5.224 294 967 296; underline for legibility POSIX::floor \$x my $x = 0x1234_5678;$ underline in hex is also OK my abs 0377; octal \$x my mν \$x = 0.0377: # octal also Per1 >= v5.34my \$x = 003//, my \$x = 0xffff; my \$x = 0b1100_0010; hexadecimal # binary string • double-quoted strings: perform backslash and variable interpolation of expression that begin with \$ (a scalar) or @ (an array). Hashes cannot be interpolated. single-quote strings: only perform \' and \\ substitution (to ' and \ respectively), nothing else. Single quote and double quote strings can spread multiple lines: it embeds the newline character on each new line. But \n is only expanded in double quoted strings! In single quote string it is treated as two characters; no substitution is done (as explained above). Unicode support To use Unicode literally in a program, add the utf8 pragma: $See: \underline{Perl\ Unicode\ Tutorial}, \underline{Perl\ Unicode\ Introduction}, \underline{Perl\ Unicode\ Support}\ @\ perldoc$ use utf8; Interpolates? · Quote constructs Generic Meaning Notes Literal string No Yes - Not all characters can be used as the / separator. { }, () and < > can also be q// Strings in Perl: -qq// Literal string used. quoted, interpolated qx// Command execution Yes You can use whitespace between the quote specifier and its initial bracketing characters qw// World list No my \$chuck_of_code = q {
 if (\$condition) { () and escaped m// Pattern match Yes s/// print "Salut! s/// Pattern substitution tr/// Character translation No } Regular expression • It's also possible to write: s<foo>(bar) and tr(a-f)[A-F] as well as separating them on 2 lines: tr (a-f) Array variables are interpolated by joining all elements with the separator specified by the \$" special variable (\$LIST_SEPARATOR). Character escapes Alert (bell) ESC character Any Unicode code point, by name: \033 ESC in octal (only inside \b Backspace \o{33} \x7f double quoted ESC character ESC in octal \N{LATIN SMALL LETTER E WITH ACUTE} Form feed DEL in hexadecimal strings) \N{ U+E9 } \x{263a} \n Newline (usually LF) Character number 0x263A Control-C Carriage return (Usually CR) \t Horizontal tab Force all following characters to uppercase. Ends at $\Endsymbol{\setminus} E$ Force all following characters to lowercase. Ends at $\Endsymbol{\setminus} E$ translation Force next character to titlecase ١E Ends \U. \L. \F or \Q \U Force next character to lowercase apes Force all following characters to Unicode fold case. Ends at **\E** Backslash all following non alphanumeric characters. Ends at **\E** (inside double auoted ۱F strings) \Q · bareword In Perl, a bareword refers to a sequence of characters suitable for an identifier. It's not quoted. By default Perl allows barewords to behave like strings. This is not allowed when any of use strict; or use strict "subs"; or use v5.12; is specified. Perl here-documents are a form of line oriented quoting. There are several forms of here documents, where the identifier (like EOF used below, but can be any word) **Here documents** must be placed at the beginning of the terminating line: Here docs @ Perl • Default : <<EOF: Supports variable interpolation. <<"EOF" Supports variable interpolation. Can also be written with whitespace as in << "EOF Perl here doc Double quotes: Does not support interpolation. Can also be written with whitespace as in << 'EOF';
Execute commands in a shell and return text printed on stdout. Can also be written with whitespace as in << 'EOF'; Single quotes: <<'EOF': <<`EOF`; backticks: indented: <<~EOF; Allows indenting the here-doc string. Can also use the ~ with the other forms: <<~\EOF, <<~"EOF", • Perl Regexp · Regexp Tutorial · PCRE cheatsheet · Debuggex regexp tester regex101 RegEx Pal Learn PCRE in X minutes

Current value of C errno integer variable	• \$OS_ERROR • \$ERRNO • \$!	\$1 returns the system when used in a nume returns the string fron used in string context	ric context, but n perror() when	Hash of error names to 0 or 1, set to 1 if current error is this error.	• %OS_ERROR • %ERRNO • %!	
OS detected error	• \$EXTENDED_OS_ERR					
Status returned by last pipe close, backtick command, wait, waited, or system() call.	• \$CHILD_ERROR • \$?			native status returned by last pipe close . backtick command, wait() or waitpid() or system() call	\${^CHILD_ERROR_	NATIVE}

Current value of warning switch	• \$WARNING • \$^W		Current set of warning checks enabled by the use warnings pragma	\${^WARNING_BITS	\$}
Variables related to the interpreter state	These variables provide information	ation about the current interpreter state.			
Flag associated with the -c switch	• \$COMPILING • \$^C		The current value of the debugging flags	• \$DEBUGGING • \$^D	
Current phase of the perl interpreter	\${^GLOBAL_PHASE}		Debugging support. Internal variable.	• \$PERLDB • \$^P	
Compile-time hints for the perl interpreter. Internal use only	\$^H		Values of compiled statements	%^H	
Taint mode	\${^TAINT}		Safe locale operations availability	\${^SAFE_LOCALES	5}
Input/Output Layers. Internal use by PerlIO only.	\${^OPEN}		Unicode Settings of Perl	\${^UNICODE}	
Internal UTF-8 offset caching code state	\${^UTF8CACHE}		State of UTF-8 locale detected by perl at startup.	\${^UTF8LOCALE}	
File handle Variables	See also: Perl File Handles	The following variables	are used in the Input/Output handling as well as program arguments.		
Name of current file read from <>	\$ARGV	Command line arguments of the script ← See diamond operator <>. →	@ARGV	Number of arguments minus one	\$#ARGV
Special file handle that iterates over command-line filenames in @ARGV	ARGV Special file handle that points to currently open output file when doing edit-in-place processing		ARGVOUT		
Output field separator for the print operator	 IO::Handle->output_field_separator(EXPR) \$OUTPUT_FIELD_SEPARATOR \$OFS \$, 		Current line number for the last file handled accessed	HANDLE->input_\$INPUT_LINE_N\$NR\$.	
Input record separator (newline by default)	 IO::Handle->input_record_separator(EXPR) \$INPUT_RECORD_SEPARATOR \$RS \$/ 		Output record separator	• IO::Handle->outpu • \$OUTPUT_RECO • \$ORS • \$\	tt_record_separator(EXPR) RD_SEPARATOR
Auto-flush control order of output @ Perl Maven Suffering from Buffering?	HANDLE->autoflush(EXPR) SOUTPUT_AUTOFLUSH \$ Solution		Last read file handle	\${^LAST_FH}	

Perl 5 Input/Output

Perl 5 Statements

Loop control	See perlsyn for more information on Perl syntax	which includes declarations, blocks, loops, labels, subrouting	nes, etc
Use the last and redo inside a naked block of code to control looping.	loop control keywords: • last of: exits the loop. • next of: starts the next iteration of the loop. • redo of: restarts the loop block without evaluating the condition again.	The last , next, and red loop control keywords work in the following constructs: • while (condition) { } • until (condition) { } • for (init; condition; continue) { } • foreach array { } • naked block: { }	Notes: • The while and foreach loops may have a continue block: executed before evaluating condition again, which corresponds to the 3rd part of a for loop statement. See this @ stackOverflow. • Blocks can be labelled of as targets to last, next, and redo

Statement modifiers	• if EXPR • unless EXPR • while EXPR • until EXPR • for LIST • foreach LIST • when EXPR • do block	The for and foreach statements impose a list context; the complete list is processed. Therefore a loop like the following trying to stop on a line that has "_END_" on it will not work since it reads all of STDIN: foreach (<stdin>) { last if ?_END/; ; }</stdin>	The while statement imposes a scalar context; it takes one line at a time from <stdin> and the following code works properly: while (<stdin>) { last if /_END/; ; }</stdin></stdin>
Conditional statements			

Perl 5 Subroutines

Perl subroutines				
subroutine &	Why we teach the subroutine ampersand Why should I use the & to call a Perl subroutine	ne? @ StackOverflow	Another point of view: Subroutines and Ampersands	
Subroutine Prototypes	An older Perl feature. Clashes with subroutine sign	gnatures as of Perl v5.20). In Perl >= v5.20 put the :prototype attribute before sul	broutine prototype parenthesis.
Subroutine signatures • Perl >= 5.36: Stable • Perl >= 5.20: Experimental See: Use v5.20 subroutine signatures	Exactly zero arguments	()	Zero or 1 argument, no default, unnamed:	(\$=)
	Zero or 1 argument, no default, named	(\$val=)	Zero or 1 argument, named, with default	(\$val=1)
	exactly 1 named argument:	(\$val)	Exactly 2 arguments	(\$v1, \$v2)
	2, 3 or 4 arguments no defaults: (\$v1,	\$v2, \$=, \$=)	2,3 or 4 arguments, 1 default:	(\$v1, \$v2, \$v3='a', \$=)
	Two or more, any number of arguments.	(\$v1, \$v2, @)	Two or more arguments, remainders into a named array:	(\$v1, \$v2, @rest)
	Two or more arguments: an even number	(\$v1, \$v2, %)	Two or more arguments, remainders into a named hash:	(\$v1, \$v2, %rest)
	Class method	(\$class,)	Object method	(\$self,)
Variables in subroutines	global by default			
	my local, lexical scope, non persistent			
	state Local, lexical scope, persistent	Perl >= v5.10	Restriction: in Perl < v5.28: array and hashes state cannot	be initialized in list context.
	our creates a lexical scoped alias to a p	ackage variable		
	local			
Returned value	The result of the last evaluated expression is i The return operator can be used but it's not re The subroutine can return a scalar in scalar co Inside the subroutine, use the wantarray fu	equired unless used to chontext or a list if called in		e).

Perl 5 Built-in Functions

Perl Functions Perl syntax	To get information about a Perl function from the command line use the perldoc -f command. To get information about print use: perldoc -f print
! Cautionary notes	
each keyword is broken Use <u>Var::Pairs</u> instead.	Do NOT use the built-in each. It is broken, as described by <u>Damian Conway</u> in his <u>Modern Perl Best Practice O'Reilly course</u> , section control structure. • each is not re-entrant: • nested loops of each over the same hash does not work as expected and will create infinite loop since the nested loop each juts iterates from where the first loop each left it. • Exiting the loop leaves the state of the each internal pointer at the current location. • If you use each on the same hash later it will resume from where it left, it will not start form the beginning.

Perl 5 Modules

Perl Modules				
Perl core modules	• How to d	How to detect where a module is installed : perldoc -1 Module		
Modules @perltutorial Modules Using simple modules of	do	Looks for the module file by searching the @INC path. Performed at run time (and therefore can be done conditionally). If Perl finds the file, it places the code inside the calling program and executes it. Otherwise, Perl will skip the do statement silently. The "included" code does not have access to the lexical variables from the main program.		
	require	Loads the module file once, also teaching the @INC path. Performed at run time (and therefore can be done conditionally). • If the require for the same file appears twice, Perl ignores it. Perl will issue an error message if it cannot find the file (as opposed to do)		
The normal way to access Perl modules ➡	use	Similar to require except that Perl applies it before the program starts: it's done at compile time. • Therefore the <u>use</u> statement cannot be invoked inside conditional statements such as if-else. Used often to include a module in a program.		

PerlTidy formatting control

	· o····uy · o····ius		
perItidy option	Option	Impact	
indentation style	-bl, opening-brace-on-new-line brace-left	 Without this option (the default) the code indentation style selected is K&R style. With this option, the indentation style is Allman/BSD style.
